Even if the colitis had been originally due to some other cause—*e.g.* dysentery, typhoid—it would have been intensely aggravated and complicated by this additional septic infection. I have seen many similar cases, and the connection between oral sepsis and colitis is by no means sufficiently recognized.

CASE 4. "*Septic anemia.*" A patient had suffered from anemia for six or seven years. Five or six years ago the anemia was so marked that she was warned by a distinguished surgeon who saw her that it might become "pernicious." When seen by me (1907) she was leading an invalid's life, suffering from chronic anemia, weakness, giddiness, and palpitation, going about from place to place in search of health. Her history was the following: For the last twelve years she had had pains, very acute, of a

neuralgic character over the right frontal region, and this was followed by a discharge of pus from the nose, followed by a similar attack the following winter. From time to time there was tenderness over the right frontal region with increase of discharge. She was sent to me by a well-known nose specialist with the following note: "She has a chronic, foul empyema of the right frontal sinus, and there is muco-pus in the corresponding antrum. Whether these conditions cause the anemia I do not know; they do not help its getting better. My suggestion is that she should let you relieve her anemia as far as possible, and when she is well enough she might have the sinus dealt with." My own opinion was quite definite. The whole history and the degree of the blood change—viz, 50 per cent. of hemoglobin—satisfied me that the anemia was "septic anemia," and that it owed its origin to the suppuration of the frontal sinus. I therefore recommended that this latter should be dealt with at once. This was done, and the patient left the home in a few weeks' time entirely cured of her ill health and anemia, from which she had suffered for six or seven years.

CASE 5. "*Septic anemia.*" A patient, age sixty-four, sent to me on September 8th for severe anemia, from which he had suffered since February. Red corpuscles 41 per cent., hemoglobin 40 per cent., leucocytes 5000. No history of loss of blood. I suspected septic anemia and looked for possible causes. I found he had only five teeth markedly septic (oral sepsis 3°), with two small necrosed roots buried in the gum of the right upper alveolus, the gum margin and alveolus being much thickened. The right cheek was somewhat swollen and puffy, with some pain in the left side and tenderness of the last molar. On inquiry I learnt that at the beginning of the illness he had an aching tooth, and went to a dentist who supplied him with a set of plates ill-fitting and uncomfortable, which had to be rejected; then supplied another set which also had to be rejected. (The dentist, it will be seen, failed to recognize the actual septic trouble presented by the remaining teeth.) The patient was placed in a home on September 14th. On transillumination no antrum disease was discovered. I had the five teeth extracted with difficulty, owing to chronic osteitis. On September 20th the corpuscles and hemoglobin had risen to 49 and 58 per cent. respectively, and the patient left the home on September 25th looking well, with 75 per cent. of corpuscles and 75 per cent. of hemoglobin. By October 18th he had 84 per cent. of hemo-

globin, and on November 17th he had 91 per cent. of corpuscles and 94 per cent. of hemoglobin, and was looking in good health.

CASE 6. *Septic anemia.* A man was admitted into a surgical ward on account of gastric symptoms with some hematemesis, suggestive of cancer. On examination nothing surgical was found justifying operation, but his anemia was most profound, and he was transferred to my medical ward. On examination I considered the degree of anemia to be too great to be accounted for by any loss of blood there had been, and there was marked fever. I therefore examined him for other causes. The gums were very pale and clean, and the teeth good with the exception of one upper bicuspid. Even on inspection I drew the attention of my class to its importance as a possible seat of hidden sepsis. On examining it a teaspoonful of pus burst from it. On further examination by transillumination the antrum above showed a deep shadow. The necrosed root was extracted and the antrum opened up and found full of the most offensively smelling pus. Between the time when he was first examined by me and the operation the pus discharged from the socket of the necrosed tooth was about two or three teaspoonfuls daily. He had swallowed and absorbed this daily—probably for many months, possibly years—with resulting gastritis and anemia, and he was transferred from the surgical to the medical ward because his condition was essentially a medical one, not a surgical one (!). The condition was one of oral medical sepsis, unlooked for, unrecognized, due to the sepsis produced by one septic root, which had probably "never given him any trouble."

CASE 7. *Septic anemia as a complication of phthisis.* A man suffering from advanced phthisis looked so exceptionally pale and anemic that had he had no phthisical signs in the lung he might well have been considered a case of anemia. His pallor and anemia, however, were not connected with his phthisis, but with the extremest degree of oral sepsis which he also presented. His health greatly improved when the condition had been dealt with. His anemia was largely the anemia which I have termed septic anemia.

CASE 8. *Septic anemia as a complication of chronic nephritis.* A patient suffering from chronic nephritis may, and often does, present an extremely anemic appearance, and in many cases a very severe degree of anemia may be present in the blood. But that also

is not necessarily a result of his nephritis, but may be, and often is, due to co-existing oral sepsis, sometimes of an extreme degree. So far from his anemia being the result of his nephritis, the nephritis may be, and, in my experience and judgment often is, largely a concurrent effect of the sepsis causing his anemia.

CASE 9. *Septic anemia complicating gastric ulcer and chlorosis.* A girl is admitted suffering from the symptoms of gastric ulcer, and she may, and often does, present an extremely anemic appearance. In her case the anemia is promptly designated chlorosis, but it is not necessarily wholly of that character. For she may, and frequently does, present an extreme degree of oral sepsis. This sepsis is, in my observation, largely the cause not only of her anemia but also of the gastric ulcer. Her trouble is by no means only gastric ulcer; both the gastric ulceration and her anemia have originally been caused by the overlooked sepsis of her mouth. They are really septic in their nature, and if the temperature of cases of gastric ulcer be watched it will be found that a certain amount of fever is very often present. And a still more interesting practical result may be noted—viz, that on removal of the oral sepsis the three conditions of gastric trouble, anemia, and fever clear up together.

CASE 10. *As a complication of nephritis.* A patient suffered from chronic Bright's disease, and presented all the usual symptoms and features of that condition—urinary changes, vascular changes, eye changes, edema, headache, drowsiness, etc., including also a varying degree of fever. The temperature suddenly rose, and erysipelatous cellulitis of one side of the face appeared. The condition thus appeared clinically as one of chronic Bright's disease, complicated by erysipelas. On examination a deep ulcer with much stomatitis was found on the buccal mucous membrane of the affected cheek. The condition then appeared clinically to be kidney disease complicated by erysipelas and ulcerative stomatitis. On further examination the ulcer of the mouth was found to be directly in contact with an intensely septic molar root, and many other teeth showed marked septic gingivitis, with tartar deposit and pockets (septic periodontitis). These latter septic lesions had obviously been there for years. The ulcerative stomatitis and the erysipelas were not sequelæ of chronic kidney disease, but the direct manifestations of an entirely different disease—viz, septic infection which had probably existed for many

years. The irregular fever presented by the case was also septic. We had thus two intercurrent conditions—kidney disease and sepsis. The latter is euphemistically termed a “terminal” infection, meaning thereby that it has come on toward the end of the patient’s chief disease. But this infection was not “terminal,” was not determined by the kidney disease. It had existed for many years prior possibly to the nephritis, and the continuous excretion during these years of its toxins was quite capable of producing a chronic tubular nephritis; or, failing that, was certainly aggravating any nephritis due to other causes.

AS A COMPLICATION OF SPECIFIC FEVERS.

The following cases show to what extent oral sepsis complicates specific fevers, such as scarlet fever, typhoid, diphtheria, and the striking benefits to be got from its removal.

In 648 cases of scarlet fever admitted into the London Fever Hospital under my care in the four years 1904–07, the incidence of oral sepsis, carefully noted by myself, varied from 25 per cent. to 43 per cent. The effect of oral antiseptics—the removal as far as possible, immediately on admission, of every trace of oral sepsis around the patients’ teeth and gums by daily swabbings with 1:40 carbolic acid solution—throughout the earlier part of the disease was very striking. The chief complications of the disease were reduced as follows: The incidence of secondary adenitis was reduced from 9.6 per cent. in 1904 to 3.3 per cent. in 1906, and 1.8 in 1907; of cellulitis of the neck from 5.2 per cent. in 1904 to 2.8 in 1906, and *nil* in 1907; of glandular suppuration from 1.7 per cent. in 1904 to 0.5 in 1906, and *nil* in 1907. The striking improvement was due to the increasing care taken by myself and by my residents and nurses under my instructions. In only one or two cases out of the whole series were any teeth extracted.

PRINCIPLES OF TREATMENT.

What are the general principles of the treatment applicable to medical sepsis? The first and most important is curiosity

about and careful observation of the actual character and degree of the septic foci present in the mouth (nasopharynx or elsewhere) in every case of medical disease. This cannot be made by a cursory glance into the mouth, and a general conclusion to the effect that the “teeth are fairly good,” or the mouth “fairly clean,” or that the mouth “requires to be seen to.” If you look closely into the mouths of your patients and note what you see you will observe every degree and variety of septic gingivitis, every degree and variety of septic ulceration, every degree of tartar deposit as a great effect of this septic inflammation and ulceration, every degree of suppurative inflammation of the gums, every degree and effect of septic periosteitis and periodontitis with formation of pockets and loosening of teeth, every degree and effect of septic osteitis—*e.g.* rarefying osteitis, causing recession of the bone socket, or formative osteitis, causing thickening of alveolus; every degree and variety of septic caries and necrosis of the teeth; and as a result of all these conditions, singly or combined, every degree and variety of septic stomatitis, simple, ulcerative, gangrenous. You will see all this in infinitely less time than it takes to examine a specimen of the gastric contents, or of the feces, or of the urine, or of the sputum; in far less time and with far less labor than it will take you to examine the nose, or the nasopharynx, or the larynx; in far less time than it takes you to examine the heart, or the liver, or indeed, any other organ of the body. In particular cases you will observe that all these septic conditions are produced, or intensely aggravated, by tooth-plates covering necrosed roots, by amalgam and gold fillings which have become septic, by porcelain crowns with gold collars, by gold caps over diseased teeth, gold bridges and other gold fixed dentures which, however good to begin with, are never really aseptic, and are liable to become extremely septic. All these you can observe in a few minutes if you look for them—in less time, almost, than it takes to mention them.

The prime indication in treatment is thus to recognize the septic infective nature of these mouth lesions and their true relations to each other—to recognize which are the causes and which are the effects.

As I have shown, the course of the septic infection is from the gums to the periodontium (periosteum) of the root, and thence to the bone of the socket. The results are septic gingivitis with ulceration, septic periodontitis (periosteitis) with ulceration (pocket formation), rarefying osteitis of the tooth itself, or of the socket with loosening of the tooth. As a result and accompaniment of the whole of these processes, we have the formation and deposition of tartar in larger or smaller amounts on the edges of the gums, in the pockets, or on the tooth itself. The prime causal factor in all these processes is the septic infection; all the other processes—gingivitis, periodontitis and periosteitis, osteitis, and tartar deposits—are the results of this septic inflammation and ulceration.

I am accustomed to ascertain the degree of oral sepsis present in every case by close examination of the condition of the gum and bone around each tooth, and to indicate the degree of sepsis—whether slight, moderate, or severe—by the figures 1°, 2°, 3° respectively. In many cases these figures do not suffice, for the degree of sepsis is so great that it can only be expressed by figures up to 7° or 10°. The patient may have all his teeth good, excepting one or two, and yet these may present such a degree of septic gingivitis, or ulceration, tartar deposit, or necrosis, or there may be so much tartar deposit in connection with one or more or all of his teeth, that the degree of sepsis is really severe—3°, 5°, or 7°. Or he may present a veritable mausoleum of gold work in his mouth in, on, and around his teeth, and be regarded as having his mouth “well cared for” and “thoroughly set in order,” when, as a matter of fact, the degree of sepsis and necrosis covered and hidden by the gold is perfectly appalling (10°). I speak from experience. I have had many such cases, and they are the most

trying and pitiable cases with which one has to deal, for they are produced by dentists. The worst cases of septic gastritis, enteritis, and colitis, of ill health, anemia, obscure septic fever, and other manifestations of medical sepsis, are in my experience those in which the greatest so-called “care,” the greatest amount of “American skill” in the shape of gold work, has been bestowed on the mouth. For the patient refuses to have it touched; he has paid much for it, and has been told by his dentist that it represents the highest dental skill. As one of them put it to me, “For the life of him he could not see what connection it had with his condition”—in his case, one of continuous ill health, gastric and intestinal trouble, and finally of anemia, from which he had suffered for twenty years. His death shortly afterward “saw” the connection.

➤ In observing the degree of sepsis in my hospital cases I am in the habit of dressing the septic wounds. The method I employ is to swab the edges of the gums and teeth with cotton and 1:60 carbolic in order to clean off pus, and to enable me to see the character and extent of the underlying wounds. The wounds are thereby dressed at the same time that they are being examined, and all the superficial sepsis is gotten rid of. This antiseptic dressing of the gums should be carried out daily so long as open wounds are present, by the nurse or by the patient himself; and it is astonishing how quickly the septic conditions of the gums are improved thereby, and how quickly the patient feels and shows by his appearance the benefit of this antiseptis.

Both the observation of the lesions and the treatment here described can be carried out in almost as short a time as they can be described. Pus is removed, pieces—sometimes masses—of soft tartar can be tilted off the edges of the gums, the foul, bleeding wounds lying underneath them are exposed, and simultaneously dressed. This treatment is applied irrespective of the presence or absence of deeper-seated sepsis—such as that connected with carious or necrosed

teeth. For even if such are present, as they so often are, the removal of the superficial sepsis is a great boon to the patient, since if left it would be swallowed. Moreover, if the teeth have to be removed, the preliminary dressing frees the wounds around the necrosed teeth from much of their sepsis, and thus prevents the risks of further infection of the fresh wounds created by the removal of the tooth.

A further and by no means the least important advantage of the simple antiseptic measures here described is this: The patient himself learns for the first time that care of the teeth does not necessarily mean extraction of teeth; that, short of extraction, much can be done without any discomfort or pain to himself; moreover, that he himself can in many cases carry out the necessary antiseptic measures. Weak, nervous, highly-strung patients, who at first absolutely refuse to allow anything to be done to their mouths, will, after a short experience of antiseptic dressing, of its freedom from pain, and of the benefits they experience from it, consent without demur to the removal of their carious roots. In one such case under my care, admitted very ill with a long-continued fever of unknown nature, the patient ultimately consented to have ten or twelve necrosed roots removed, and went out quite well—a marvel to herself and to the doctor who sent her in, thinking that she had some obscure malignant or tuberculous disease. The temperature, which had ranged between 101° and 103° for many weeks, fell to normal on the day after the removal of the septic roots.

These are very simple principles of treatment for a condition that carries with it so many ill effects—so it may be said. Yes, the principles are simple—they are *only* (!) those of observation and recognition and removal of the sepsis responsible for these effects. They are of the same simple character as those underlying the washings and scrubblings of his own hands and the skin of the patient which the surgeon carries out with such patience and ritu-

alistic care. They have the same object—namely, the removal or prevention of any sepsis that can possibly introduce septic infection into the body. Like these measures, they are most effective when carried out by the doctor himself, not left to others. They differ from the antiseptic measures of the surgeon in one respect; they are not carried out amid the same impressive antiseptic surroundings. They therefore lack the impressiveness of the surgeon's antiseptic precautions both for the patient and the medical onlooker. But this is a fault that can, and will, I hope, in the near future, be remedied. For the evil of sepsis in the mouth is a very prevalent one and can never be adequately dealt with by driving every sufferer from it through the already overtaxed and overburdened hospitals of the dental profession. Even after it is dealt with antiseptically in the manner above described by the doctors and surgeons whose cases it complicates, there will always remain sufficient for the dental surgeon to undertake in his own sphere.

The surroundings which I would fain see provided in both general and dental hospitals and children's schools for carrying out these initial and all-important antiseptic dressings of the mouth would be special dressing-rooms free from all costly appliances of dental chairs and dental apparatus, and furnished simply with the simpler antiseptic furniture of a surgical dressing-room. If patients could learn that they could have their gums and teeth antiseptically dressed by a competent nurse without any pain or discomfort to themselves, the evil of oral sepsis could be greatly prevented or kept in check. For they would learn from this experience what they cannot learn now—namely, the antiseptic objects and the benefits of cleanliness of the mouth. As one hospital patient put it, "No one had ever told me before."

These principles of treatment are indeed simple; they are only those underlying the whole practice of antiseptic surgery—namely, removal of sepsis whenever it is causing ill effects and can

be got at. If they can be put into practice in the domain of medicine to prevent or get rid of some of the most prevalent diseases in medicine, as it is my experience they can be, it is the duty of the medical profession as a whole and each member of it within his degree to help to carry them into practice, and to devise the proper measures in their hospitals to enable them to be carried out.

The evil is so common and widespread that it is impossible to deal adequately with it—so it may be said. The same plea might have been urged in connection with every other great practical advance in preventive medicine—*e.g.* the sanitary measures for the prevention of typhoid and other water-borne diseases. To deal effectively with such diseases, to teach people how to be clean in their

sanitary arrangements, must have appeared an almost hopeless task when sanitary science was first put into practice. But everything can be done in time, if the principles underlying our efforts are sound.

So with this great evil of oral sepsis and its manifold ill effects, far more widespread in their extent and no less severe in their character than those connected with typhoid or even with tuberculosis. The plea of helplessness to deal with it, I submit now, as I did in my first papers on the subject, is a singularly poor one to be put forward or given any support by the medical or surgical profession, at whose instigation the most elaborate and expensive equipments of hospitals have been and are daily being carried out.

Improved Method of Casting Splints and Use of Headgear in Treating Fractured Jaws.

By JAS. EDWARD AIGUIER, Ph.G., D.D.S., First Lieut. D.R.C., U. S. A.,
Philadelphia, Pa.,

INSTRUCTOR EVANS DENTAL INSTITUTE, UNIVERSITY OF PENNSYLVANIA.

DENTAL surgeons of today, especially those connected with the army, are paying considerable attention to the treatment of jaw injuries.

Having been associated with the teaching staff of the Officers School of Oral and Plastic Surgery, at the Evans Institute (Univ. Pa.), established by the Surgeon-general of the United States Army for the training of surgeons and dentists, this experience being supplemented by the twenty-odd jaw cases which came under my observation in the oral surgery clinic during the past winter, the great necessity for simplifying the method of treating jaw injuries was forcefully brought to my attention. In the treatment of fractured jaws one soon realizes that a universal splint can never be de-

vised, as each accident case is a law unto itself, and only after careful diagnosis can the proper splint for the particular case in hand be decided upon.

However, there are many instances in which the basic principles of a universal method of making splints can be applied. Time is the all-important factor in making splints, especially in the present war work. It is well known among surgeons who have done considerable work with fractured jaws that a splint should be applied within twenty-four hours, for after fibrous union begins it is difficult, and the longer the delay the more difficult, to get absolute reduction of the fracture: in some cases it is impossible without surgical interference. Simplicity is another important factor; the simpler

the method for making these devices the greater the benefit it will be to the patient. Not only in war work, but in general practice the dental surgeon is inclined to resort to the method that requires the least time and the least amount of work; for in general practice, in the usual fractured jaw case the patient is unable to pay an adequate fee for the service.

The swaged metal splint has undoubtedly proved most satisfactory and met with most favor in the treatment of war cases, according to the articles written on this subject, and in general practice the same is true. However, the swaged splint necessitates the making of dies and counter-dies and the tedious process of swaging and soldering, in which there is always the possible chance of not getting the proper articulation.

With these ideas in mind the writer has devised a method of casting splints which he has put to practical use for several months on a number of cases, and has proved its worth in the matter of saving both time and expense, and in its general usefulness.

Cast splints are by no means new. Port in 1890* and 1905 described a cast splint of the Gunning type made of tin, also Hauptmeyer† in 1908 described a method of using cast splints of tin in connection with the headgear. Cole and Bubb (*British Medical Journal*, 1916) used the cast interdental and Gunning splint of aluminum.

A cast splint made of a metal which in general has proved to be well borne in the mouth, a metal that will melt at a low temperature, and one that will cast without pressure or suction, thus eliminating the use of a casting machine, would seem to be particularly desirable for war work.

Tin has much in its favor, for the following reasons: During the last sixty

years, tin, alone or alloyed with some other metal, has been used for cast lower dentures. During this period thousands of these dentures have been made and worn, and up to the present date there is but a single case of "tin poisoning" reported.

The report of this case appears in the *Journal of the American Medical Association* (April 6, 1918, p. 980) and is looked upon by authorities as a case of individual idiosyncrasy, which may have resulted from the use of impure tin, or the alloying may have caused the formation of other compounds. According to the report of the case, the metal showed evidence of corrosion in spots, which would lead one to suspect impurity. In consulting works on toxicology there is no report of poisoning from pure tin, but a few cases of poisoning are reported from *tin salts*, which of course are soluble.

The National Canners' Association research laboratories, Washington, D. C., make the following report on the toxicity of tin: "It is well known that the earlier workers on tin poisoning were altogether wrong, and that the toxicity of tin is very slight, if indeed it can be demonstrated."

I have consulted several toxicologists on the subject, and they are all of the opinion that pure tin will *not* cause poisoning.

The low fusing-point of tin (232° C., 450° F.) is another important feature in its favor. This fusing-point is sufficiently low for the metal to be melted over any kind of a fire, and consequently a special furnace or blowpipe is not necessary. By experience we find that tin can be cast without pressure, giving the finest details, and thus eliminating the necessity of a casting apparatus.

EXAMINATION AND HANDLING THE PATIENT.

The surgeon or dentist should first examine the field of injury very carefully to determine the amount of damage and to locate the line of fracture, after which impressions of the jaws are taken in soft plaster. The best material for this work

* Port, "Dental Schiene aus Zinn," *Aerztl. Intelligenzblatt*, No. 9, 1890.

† Hauptmeyer, "Ueber erfolgreiche Verwendung von Kieferschienenverbände bei Frakturen und Resektionen mit besonderer Berücksichtigung der Zinnscharnierschiene," Leipzig, 1908.

is known as "Byrtis" plaster, as it can be very readily separated from the model by dropping in boiling water, thus saving considerable time. Before taking the impressions the teeth surfaces are coated with vaselin. The impression of the *un-injured* jaw is taken first, as this causes very little discomfort to the patient. Then the impression of the injured one, which is more painful, is taken, using very soft plaster and applying it to the surfaces of the teeth with the finger or spatula before inserting the tray filled with the soft plaster. Cutting and trimming of the trays are sometimes required, and often it is necessary to make trays of modeling compound to fit the individual case, and sometimes to take the impressions in sections. The use of vaselin also facilitates the separation of the plaster after the tray has been removed. Radiographs are now made; they are *absolutely essential* in treating these cases. In the meantime the models are poured, and, the patient having now returned, all infected roots present are removed and the teeth are scaled if necessary. Any tooth in the line of the fracture, and teeth with fractured roots, must be removed. The mouth is cleansed with potassium permanganate solution (1:5000) and Talbot's solution of iodine is applied to any lacerations or badly inflamed areas. Next the fracture is reduced and the teeth wired until the splint is ready. The jaws are held in place by the aid of the headgear devised by the writer and described below, with its rubber-dam chin support. Instructions are given regarding the diet, which must be confined to liquids taken by the aid of a tube. The mouth must be rinsed thoroughly with normal saline solution every hour or two, and especially after meals.

TECHNIQUE OF MAKING THE SPLINT.

First saw through the model of the injured jaw (Fig. 1) in the line of fracture, and articulate the teeth to those of the other model, waxing the pieces of the cut model together in proper relation. With the aid of the face-bow set the models on the articulator (Fig. 2), using

the Gysi, Twentieth Century, or any type of articulator to which the face-bow can be adapted. Each cast is now covered with two layers of tin foil (No. 60), bur-nishing each layer separately and per-

FIG. 1.

fectedly to place, where they are held by sticky-wax. The surface of the foil is then oiled, and a sheet of Kerr's casting wax No. 24 ($3\frac{1}{2}$ by $3\frac{1}{2}$ in.) is adapted to the teeth over the foil.

FIG. 2.

The wax is chilled from time to time with cold water while trimming it on the upper and lower teeth to the gingival margins. Do not allow the wax to extend beyond the margins, as this will in-

jure the soft tissues, and do not trim the wax short of this line, as a certain amount of strength will be lost. The

FIG. 3.

occluding surfaces are slightly heated over a flame, bringing them together with sufficient pressure to get absolute con-

FIG. 4.

tact. (Fig. 3.) Windows are cut in the wax to show that the teeth are in proper occlusion when the splint is cemented to place. The best locations for these

windows are over the labial surfaces of the central incisors, premolars, and molars of both upper and lower jaws (Fig. 4), being sure to have a window on *each side* of the line of fracture. This is very essential in order to assure the operator of the absolute reduction of the fracture when cementing the splint. The space on the lingual surface between the upper and lower wax forms must be filled with wax to make a smooth, self-cleansing surface; this also adds strength to the splint.

The waxed piece is again chilled with cold water, the splint form removed, and a core with three sprues added (Fig. 3), one sprue attached to the symphysis and one to each heel. The core is made as large as possible, to obtain weight of metal, using a sheet of base-plate wax and making a cylinder. It is not necessary to make this a solid core, as the cylinder is more easily removed and saves considerable wax. The core can be made of a metal tube slightly covered with melted wax or oiled to facilitate removal; this would save time where any great amount of splint work was being done. Note that casting wax is used for the splint form, but base-plate wax is used for the core and sprues. The method of using two cores, one at each heel as an inlet and outlet, has not proved very satisfactory in our work, for the reason that in order to get detail the cores have to be made so long as to require considerable more investment and therefore more time to dry out.

Cover the entire wax splint forms with silex and casting plaster in the proportions of 3 parts of silex to 1 of plaster, painting it over all surfaces with a small camel's-hair brush. (Fig. 5.) The waxed model is now placed in a casting flask. (In an emergency a casting flask may be made with a tin can cut and bent to the dimensions of about $1\frac{1}{2}$ by $3\frac{1}{2}$ by $3\frac{1}{2}$ in.) The investment is now completed with sand and casting plaster in the proportions of 1:2. The investment is allowed to harden for one hour or more, the flask put over a low fire, the heat being gradually increased until all the wax is burned out. Allow the flask to cool so that the hand can be held near it without discom-

fort. Moderately hot melted block-tin is poured into the investment, relying on the weight of the metal, provided for by the large core, to give a proper cast. The casting is allowed to cool thoroughly before removing, and never chilled with cold water, as this may have a tendency to destroy some of the details of the casting.

After the removal of the casting the sprues are cut off with a frame saw or

FIG. 5.

other suitable instrument (Fig. 6), any rough edges on the splint are trimmed with a plug-finishing bur or vulcanite file, using pumice and brush wheel for the final polish. The splint is tried on the model, first removing the tin foil, to be sure of its perfect adaptation. Sometimes while investing the wax form it loses its proper shape, as the wax is very thin and easily distorted. If this should occur, the pliability of the metal will readily permit its correction by simple thumb pressure. This is another important point in favor of tin. The splint is now ready for use. (Fig. 7.)

The above-described splint is applicable to cases in which there has been very little or no loss of bone and there are few or no teeth missing. In mouths in which

FIG. 6.

many teeth have been lost, accompanied by the loss of bone substance, it is advisable to bridge the spaces with nickel-silver wire (gage No. 13), using one or two strands on the labial and lingual sur-

FIG. 7.

faces according to the strength needed. (Fig. 8.) Wax these wires into place, and in order to have the casting adhere to them they must be previously tinned. The tinning is accomplished in the following manner: The wire is dipped in a saturated solution of zinc chlorid, then

wrapped with a single layer of tin foil No. 4. The wire is then held over a flame until the foil fuses, which it does at a very low temperature: it is then re-

lugs are soldered to the wire, timed as above described, and then waxed to place. Likewise if the case requires an open bite for feeding or for cleansing the mouth.

FIG. 8.

FIG. 9.

moved and brushed with a toothbrush or rubbed with a cloth. Another method of tinning is to slightly heat the wire, apply zinc chlorid and dip in melted tin,

pillars of suitable size to give strength can be waxed at suitable places. Fig. 9 illustrates a modified Gunning splint, with better adaptation, less bulk and

FIG. 10.

after which the wire is rubbed with a cloth.

If it is desired to make individual splints for the upper and lower jaws with lugs for wiring the two together, these

weight, more slightly and easier to keep clean.

The Kingsley splint can be cast of tin (Fig. 10), instead of using vulcanite, thereby saving considerable time and pro-

ducing a splint with practically no difference in weight from the vulcanite splint. There is also in its favor the fact that the cast splint is more accurate than the vulcanite.

CEMENTING THE SPLINT.

Before applying the splint the patient is given a hypodermic injection of a quarter of a grain of morphin sulfate and $\frac{1}{160}$ grain of atropin sulfate to relieve the pain and check the flow of saliva. The splint is tried in the mouth, reducing the fracture carefully, and noting by the windows in the splint that the teeth are in proper occlusion. The splint is then removed, the mouth sponged dry, and gauze placed in the vestibule and vault of the mouth to take up any secretions. The teeth are wiped with alcohol and dried with an air-blast, and the splints wiped with alcohol and dried.

The cement is mixed very thin, but in quantity, a copious amount being applied to both sides of the splint; the gauze packing is taken out and the splint quickly placed into position, again noting the occlusion by means of the windows. The jaws are held together with considerable pressure for from fifteen to twenty minutes. In the meantime grease the lips well with vaselin or cold cream, to prevent injury to the dry tissues. If this precaution is not taken, herpes will sometimes develop. The excess of cement is now trimmed away, and the headgear, with rubber dam for additional support, applied as in Fig. 11.

For fractures with no great loss of bone substance, splints are allowed to remain in place for from five to seven weeks, but where there is any great loss of bone substance they must be retained for a much longer period.

TECHNIQUE FOR THE REMOVAL OF SPLINTS.

To remove splints, cut through the metal with a wheel bur, using one the thickness of the metal, cutting from the occlusal to the gingival edge along the median line of each tooth surface, or,

tin being a soft metal, a knife or chisel can be used; bend back the metal, and remove the splint. After the removal of the splint the teeth should be scaled and polished, and the gum margins touched with Talbot's iodine solution.

NECESSITY FOR HEADGEARS.

The use of head appliances for maintaining fixation of the jaws dates back to the time of Hippocrates, and during the middle ages Celsus, Galen, and Avicenna used chin supports for fractured jaws. Ambroise Paré used and described these devices in the middle of the sixteenth century. Piperno writes of one used by Solda in the middle of the eighteenth century.

Within the past fifty years headgears have come into prominence in treating fractured jaws, and the following men have contributed special forms: Bean, Bouisson, Cravoisier, Graefe, Hamilton, Kingsley, Schroder, and others. However, none of these were universal, nor would they answer the present demand in war surgery. Blair, in his latest edition of "Surgery and Diseases of the Mouth and Jaws," describes a headgear used by Kazanjian during the present war, made of webbing and vulcanite.

The numerous reports of war cases have shown the necessity for a headgear that could be used universally for all face and jaw wounds, one that could be adjusted to any head and that would not only act as a chin or splint support, but answer many other purposes, *i.e.* as support for pressure pads in plastic operations, support for pressure pads to arrest hemorrhage, also as a support for nose-plugs and to hold saliva aprons, etc., but most important of all, to save bandage material, as the average head bandage requires from five to ten yards for each dressing.

With these ideas in mind the writer has devised a headgear which has been used with success during the past winter in the oral surgery clinic of the University of Pennsylvania. This appliance is inexpensive, being made of non-elastic webbing $1\frac{3}{4}$ in. wide, nickeled

brass buckles, zinked steel bands and nicked steel hooks and eyelets which are covered with celluloid (Fig. 11), and is adjustable in three dimensions so that it will fit any size or shape of head. The horizontal band has a zinked steel band attached with hooks at stated intervals on the anterior half, and a buckle for the adjustment of the band. The longitudinal band runs forward from the occiput and buckles at the median line of the forehead. The transverse

FIG. 11.

band runs over the vertex so that the stirrups do not interfere with the ears, with a buckle for its ready adjustment.

The zinked steel on the horizontal band gives the apparatus the rigidity which is desired in so many cases. The stirrups of heavy wire are made adjustable and will fit any pair of hooks on the band, bringing the point of support to any desired position. Rubber dam, elastic webbing, or bandage may be fastened to the stirrup and passed under the chin for support.

This apparatus can be washed, sterilized, and used again if desired.

The Surgeon-general's Office of the

United States Army has approved and adopted this headgear for the division of "head and jaw surgery."

As a definite method of procedure let us consider the following cases:

Patient H. C., age thirty-nine, on April 3, 1918, while repairing the top of an elevator dropped with the machine five stories to the basement. He was found unconscious, with a lacerated scalp and concussion of the brain, a fractured arm, and many injuries of the body. He also received a bilateral fracture of the mandible between the first and second premolars on the left side, and through the body of the ramus on the right side, allowing

FIG. 12.

the segment of the jaw to drop about one inch. (Fig. 12.)

The patient was attended by a surgeon and lay in a critical condition in the hospital for several days. Every attention was given the patient's injuries *except* the fractured jaw, as the surgeon had had very little experience with this class of cases. Radiographs of the jaw were taken, and the patient's family were informed that the jaw would never resume its normal articulation. Three days later the attending surgeon called a dental surgeon into consultation, who found the patient's general condition improved; he had recovered from the shock, but the jaw was in a very bad condition. On examination the bilateral fracture was very soon determined; severe infection with swelling and temperature was also present. After cleansing the oral cavity with potassium permanganate solution, plaster impressions were

taken and casts made, and the jaws radiographed to verify the previous examinations.

A hypodermic injection of morphin sulfate grain $\frac{1}{4}$ was given to relieve the pain when reducing the fracture. The teeth were sealed, the mouth again cleansed with permanganate solution, and Talbot's iodine was applied, after which the fracture was reduced, with considerable difficulty owing to the adhesions.

FIG. 13.

(It is to be noted that any delay in placing fractured bones in *correct apposition* is a matter of very serious import to the patient, the surgeon, and the dental surgeon, for the reason that in some cases it is impossible to get absolute reduction without surgical interference, and this may lead to infection and many pathologic sequelæ of a serious nature.) When reduction was completed the teeth were wired and additional support was

applied by means of the headgear with rubber chin support described above.

The following day the second premolar in the line of fracture was extracted, the mouth cleansed in detail as in the previous description, and a splint constructed by the method mentioned was cemented to place. During the night the patient developed violent paroxysms of coughing, due to an acute laryngitis, which caused the splint to loosen. In the morning the splint was removed, cleansed and re-cemented. Codein sulfate was ordered, grain $\frac{1}{4}$ every three hours as needed, to allay the cough. As an additional support for the splint, the headgear with rubber dam beneath the chin was kept on continuously. The mouth was rinsed thoroughly once a day with the permanganate solution, and with normal saline solution every hour. The infected and inflamed areas were dried and touched once a day with dilute Talbot's iodine solution.

At the end of six weeks the splint was taken off, as the patient had recovered, and it was found that the jaws were occluding naturally. (Fig. 13.)

The writer is greatly indebted to Mr. J. T. Cologne of the graduating class of the University of Pennsylvania School of Dentistry, who has so willingly helped in the preparation of specimens, and to Messrs. A. E. and F. P. Croke for taking the photographs used in this article.

40TH AND SPRUCE STS.

CORRESPONDENCE

Radiolucency of Chloro-percha in the Radiograph.

TO THE EDITOR OF THE DENTAL COSMOS:

Sir,—The findings upon this subject, as published by Dr. Clyde Davis in your May issue, are not in accord with the results obtained by experiments made upon the same subject by myself, and as possibly he, and not I, may be at

apex, when the saw blade was deflected, and a piece of the root was removed. (Fig. 1.)

A *thin film* of chloro-percha was placed in the root-canal, the loose piece of root put back in position: the tooth was

FIG. 1.

Note that the infinitesimal amount of chloro-percha in the root-canal caused a shadow, as shown in Fig. 2.

FIG. 2.

FIG. 3.

fault, the results obtained by me are here given.

It must be appreciated that every day hundreds, if not thousands, of roots of teeth are skiagraphed, and the question of correctly interpreting these pictures is of the greatest moment.

A central incisor root was sawed down vertically through its center for about a quarter of an inch, beginning at the

now set in a socket in a mandible which was at hand, and a skiagraph taken. The result is shown in Fig. 2.

The root was again opened, the canal *well packed with chloro-percha*, and the same details again repeated. The result is shown in Fig. 3.

The object of putting the tooth in the socket before skiagraphing was to more nearly simulate mouth conditions than

was done by Dr. Davis when he skia-graphed the tooth *not* surrounded by bone.

CONCLUSIONS.

(1) A *very slight amount* of chloro-percha in a root-canal can undoubtedly be shown in a skiagraph.

(2) Where a root-canal shows no evidence of such a root-canal filling, it can be safely assumed that there is no filling

therein. And furthermore, the examination of skiagraphs of hundreds of pulp-less teeth reveals the fact that while many, if not most of them, are not filled to their apices, the conditions about the ends of the roots are *apparently* healthy.

Yours respectfully,

C. EDMUND KELLS.

NEW ORLEANS, LA., May 14, 1918.

"Iodo-Glycerole."

(See "Iodo-Glycerole," DENTAL COSMOS for January 1918, page 50.)

TO THE EDITOR OF THE DENTAL COSMOS:

Sir,—In the claim which he sets up with regard to priority in the matter of the introduction to the service of medicine of the well-known iodine and glycerin compound, Dr. Talbot is, I think, laboring under a misapprehension.

I extract from a volume ("Science and Art of Surgery," Erickson, 8th edition, vol. ii, p. 414), which lies in front of me, the following:

Injection of the sac [the author is discussing the treatment of spina bifida] with various preparations of iodine was a method of treatment which had frequently been resorted to without success before 1876. In that year, however, Morton of Glasgow suggested the use of the following preparation: Iodine gr. x, potassium iodide gr. xxx, glycerin 1 oz.

Those of your readers who may be interested in the question will notice, in the quotation which I have given, that not merely had Dr. Talbot's "mixture" been anticipated by some four years, but that, strangely enough, Dr. Morton had in his formula included potassium iodide, though not for the purpose which Dr. Talbot would have us believe.

Very truly yours,

R. WYNNE ROUW.

5 UPPER WIMPOLE ST., LONDON, ENG.

February 12, 1918.

[The foregoing communication gave rise to the following correspondence, which is self-explanatory.—ED. DENTAL COSMOS.]

MR. R. WYNNE ROUW:

Dear Sir,—I have to acknowledge receipt of your communication relative to iodo-glycerole. Before publishing your note in the DENTAL COSMOS, let me call your attention to the fact that the iodo-glycerole of Talbot does not contain potassium iodide, but zinc iodide, which confers upon the compound the astringent and doubtless antiseptic properties of zinc iodide, which in so far as they are peculiar to zinc iodide are not possessed by the formula of Morton of Glasgow as quoted by Erickson. Morton's formula utilizes potassium iodide to increase the solubility of the iodine, thereby obtaining a stronger solution in the same manner as was done in Lugol's formula, which consists of equal parts of iodine and potassium iodide with an amount of water equal to the weight of the other two ingredients, thus making a very concentrated caustic iodine solution. I am not at the present moment informed as to the date when Lugol's formula was first published, but you will see, however, that Talbot's differs essentially both from Morton's and Lugol's iodine solutions, for which reason I have thought best to call your attention to the matter, and await your further advice before publishing your comment.

Very truly yours,

EDWARD C. KIRK.

PHILADELPHIA, PA., March 12, 1918.

TO THE EDITOR OF THE DENTAL COSMOS:

Dear Sir,—Many thanks for your letter. Let me assure you that I am fully acquainted with the differences to be found in the formulae of Drs. Talbot and Morton, and that

I claim to know something of the therapeutic values of both compounds.

I shall be greatly obliged if you can find room in the columns of your journal for

the note which I have already addressed to you.

Very truly yours,

April 10, 1918.

R. WYNNE ROUW.

Replantation of Teeth.

TO THE EDITOR OF THE DENTAL COSMOS:

Sir,—In explanation of the two questions which have been raised by the reviewer of my paper at page 261 of the DENTAL COSMOS for March 1918:

The reasons why I postpone so relatively long the replantation of teeth are, first, as has been correctly assumed, to permit time for the eradication of the apical disease focus; second, to permit a certain amount of new bony formation within the alveolus, or the contraction of its lumen, because I have been taught by experience that if the root of the replanted tooth enters very tightly into its alveolus, the contact of the two sur-

faces is sure and the process of ankylosis will be prompt.

In answer to the second question, relating to the absence of radiographic data: Radiography, as applied to the teeth at the time of my three replantations, had not yet obtained very successful results for diagnostic purposes in Italy. Not having then the possibility of taking radiographic pictures myself, I had them made by radiographers in many cases, but not satisfactorily, and this is the reason why they do not appear in my article.

Very truly,

ANGELO CHIAVARO.

ROME, ITALY.

"Technique of Root Amputation."

TO THE EDITOR OF THE DENTAL COSMOS:

Sir,—On page 520 of the June issue of the DENTAL COSMOS my friend Dr. C. Edmund Kells of New Orleans has a few questions to ask regarding my paper on "The Technique of Root Amputation" as published in the May issue of your journal, as follows:

(1) After the cavity is sponged and appears "as clean as a billiard ball," why should its surface be painted with iodine? What does the iodine do to this perfectly clean and sterile surface?

Ans. The quick-drying coating of iodine-acetone is applied to the clean cavity for the purpose of furnishing a moist

surface for holding the surgical powder in place. If there is any objection to the iodine coating, a physiologic salt solution will answer, but it does not dry.

(2) What action upon this iodized, clean and sterile surface has the surgical powder?

Ans. The surgical powder facilitates the coagulation of the blood and renders the blood-clot sterile for a reasonable time.

(3) The doctor says that when a broken instrument is in the canal, it is sometimes necessary to "push the obstructing agent back into the canal."

Ans. To "push the obstructing agent back into the canal" possibly does not clearly express what I intended to say. It is to be understood, of course, that the broken instrument is pushed from the opening of the root-canal at the excised apical end into the pulp chamber, and the foramen is then closed with soft amalgam as described in the original paper under the discussion of the resection of the palatine root of the upper molars.

(4) Success is merely a relative term, as is well known. Many a surgeon has been discussing the details of a successful operation while the friends of the subject were putting flowers on the grave.

Ans. As I have stated on page 309, "as yet he (the writer) has had no oc-

casional to examine postmortem specimens." The reported 200 cases without a single failure have been operated upon within a period of a few months up to four years. In the cases in which we had occasion to examine the patient at a later period by physical means, including X-rays, no further disturbance was noted, and consequently, in our opinion, this would constitute a cure. We have of course no means of saying that this is equally true of the cases which have not returned for examination, but it is to be assumed that if trouble had arisen the patients would have returned to us for consultation.

Sincerely yours,

HERMANN PRINZ.

PHILADELPHIA, June 11, 1918.

PROCEEDINGS OF SOCIETIES

Academy of Stomatology of Philadelphia.

Monthly Meeting, Thursday, April 18, 1918.

THE meeting was called to order by the president, Dr. William A. Jaquette, at 9 P.M.

The minutes of the previous meeting were read and approved.

The report of the Council was read and accepted.

Mr. WILLIAM C. FREEMAN was introduced by the President, and spoke on the subject of the Third Liberty Loan.

Dr. ARTHUR H. MERRITT, the essayist of the evening, then read a paper entitled "The Pathology, Etiology, and Treatment of Pyorrhea."

[This paper is printed in full at page 574 of the present issue of the DENTAL COSMOS.]

DISCUSSION.

Dr. Paul R. Stillman, New York City. *Mr. President and Members,*—I came down to Philadelphia this afternoon by invitation of this society and at the request of Dr. Merritt, to fulfil the traditions of a discussor. Naturally, one would be expected under the circumstances to say that this paper was "a very good paper," but I am not going to say that; I am going to say, though, that in my opinion, at least, it is the best effort upon this subject I have ever heard. It is so rich in thought, so concise and free from verbiage, that in listening to it one seems to miss much. I shall be glad when I can have a copy to read. I shall be glad to read and study it when it is published.

As it is the traditional duty of a discussor to criticize as well as praise, I wish to take exception to Dr. Merritt's free use of the term "pyorrhea"—a word which means literally "a flow of pus." I believe this word should be limited in its use to its literal meaning, and that it should never be employed in the broad way which is still common, and in which Dr. Merritt uses it here. I prefer the more scientific word periodontoclasia or its synonym dental periclasia—a breaking-down of the supporting structures of the teeth. While periodontoclasia may not be any more euphonious than pyorrhea, it is certainly more scientific. Not every case of dental periclasia is accompanied by pus flow, yet every case of pyorrhea must have this symptom if we use the term correctly.

I wish to say a few words to you on the theme of treatment to supplement the excellent statements in the paper on this phase of the subject. Everyone who treats disease recognizes that there is some inherent force in the organism which brings about the "cure." "Man does not cure; God cures." If we are able to remove all of the factors which are contributing to the condition, no matter what that condition may be, natural forces will be awakened which will produce health. Everyone who succeeds in having his cases of dental periclasia return to health must necessarily do precisely the same things in treatment. One may emphasize the importance of one phase of treatment above another; one may see a superior efficacy in drugs, in gas, in root surgery, or in polishing operations, but if any of the several factors which are grouped in the etiology of the disease are disregarded in diagnosis, failure will result. A correct diagnosis is of paramount importance in this work. How shall we make a diagnosis? Whenever nature is in trouble and is unable to help herself out of a difficulty she hangs out a sign. Periodontoclasia is a purely biological problem where diagnosis is concerned. In diagnosis for treatment we must forget for the moment all pathology, and think in terms of biology. Pathology deals with cells

which are dead. We are interested in diagnosis for treatment only in the living cells. We must conserve and stimulate these living cells into their normal activity. Suppose we look down from our veranda and see a patch of yellow grass upon our lawn. Our interest in the treatment of this grass is instant: We investigate. In other words, we diagnose; we desire to know why the grass seems to be dying. What has caused this disease? Is it bad soil, lack of grass food, or moisture? Or has the chauffeur emptied the crank-case of the car or the cook the ice-cream freezer on the lawn? We examine, make a diagnosis, basing our treatment upon our findings, and the lawn is restored.

Now, the conditions are identical in the mouth. Nature hangs out a sign and we diagnose. One should be warned against over-treatment. Too much water will kill the cell life on the lawn, and too much treatment will discourage cell activity in the investing tissues. Experience alone will direct in the one case as in the other. One can bedevil a case by too much treatment as innocently as a baby may love a kitten to death. Cases which are advanced in disease need time for convalescence; six months or perhaps a year for many.

Dr. Merritt deserves great praise for the excellent paper which he has brought here tonight. He has given us more thought, and in fewer useless words, than is usually found in the literature of this subject.

Dr. A. W. Doubleday, Boston, Mass. I am grateful for the opportunity of being here tonight. I am thankful to your society and to Dr. Merritt for asking me. We have heard a paper that is beyond discussion. It must be, and I think has been, accepted by all of us. There are one or two points which have occurred to me during the reading of the paper that I wish to bring out, and which perhaps Dr. Merritt will speak about in concluding.

One of these is the cases of severe anemia with low hemoglobin. It occurs to me that in these cases we get a class of pus production which is always termed

pyorrhea. I can recall at least three cases in my practice. Two were in young women, about sixteen years of age. My opinion was that they were overactive in social duties, and had no time to sleep or rest. Their hemoglobin was down to about 60. I called the attention of their parents to the condition. One case was sent to Manheim, Germany, where the young woman took the iron cure. She came back to Boston much improved, and later went back a second time. Today she is as healthy a person as we could expect to see. She has been in France for a year, doing hard work, and is now back in Boston. There was a disappearance of pus, from whatever cause it may have been. In my opinion, it was the result of restoration of nearly normal metabolism in the patient.

Another case was that of a man of fifty years. He had no symptoms of what I would call chronic pyorrhea, but he had lost one tooth after another, and never did I see more than one tooth with pus coming from it at any one time. In none of these teeth could I stop this flow of pus. I did not know how. Perhaps, after hearing Dr. Merritt's paper, I might have tried. I was obliged to extract one tooth after another, all in the course of three years. I made an analysis of the man's saliva in 1917, and found tubercle bacilli present. He had an intestinal tuberculosis. This man, two weeks ago, had his right arm removed, tuberculosis having localized in that point. I think that his anemic condition had more or less to do with the pus coming from around the teeth. In none of the teeth was there a filling, and there was apparently no caries.

There is another point that I want to bring out, and that is the relation of different kinds of anemias to pyorrhea. Where we have severe anemia we have a deficiency in the lime salts and an abundance of caries, and until we correct this deficiency in lime salts, we will have a prolific carious condition. With the exception of this pyorrhetic condition of which I have just spoken, I have never found pyorrhea and caries associated. On the other hand, in severe cases of

pyorrhea in which there is calculus present I have in no case that I can recall been able to find carious teeth associated with the pus-producing teeth; and I am wondering whether caries and pyorrhea do occur together.

Dr. J. Clarence Salvas, Philadelphia. I want to congratulate Dr. Merritt on the splendid paper he has presented to us this evening. It should be read and studied, that a clearer conception and a more intelligent understanding might be gained of this distressing and destructive disease—a disease that has been much written about and much talked about, but, with all, little understood. Pyorrhea is the *bête noire* of a large majority of practitioners. I venture to say that there is not one in this audience who, if he has read but a small part of the voluminous contributions to dental literature on this subject, will not confess that he has been lost in a maze of conflicting theories. This is not surprising in view of the fact that there is as yet no agreement among our investigators as to the etiology of the disease. There is one group of able operators who believe it to be secondary to constitutional disease; another group who believe it to be an entirely local condition, and still a third group who believe that both conditions are causative factors, that is, that local irritation is the exciting cause, which is effective only where there exists a predisposition to the disease from faulty metabolism.

Pyorrhea is an infectious disease, but in contrast to other infectious diseases of the body, such as typhoid fever, measles, smallpox, etc., all of which present certain well-defined symptoms which identify them unmistakably as the disease respectively in question, there is in pyorrhea a great variation in the symptomatic phenomena presented in different conditions. You are all familiar with the case of the root covered with calcareous deposits and pus oozing from the socket, while on the other hand there is the equally common condition of the root free from calcareous matter, the root perfectly smooth, surgical treatment revealing the remains of necrotic mem-

brane, and there is more or less pus. Again there is the condition which is so common in which the investing tissues are apparently healthy but on examination a low insidious inflammation involving the subgingival tissues is found; there is invariably a pocket extending almost to the apex, and frequently an absence of pus. Thus we have three distinct conditions, but all are symptoms of the one disease.

I am particularly impressed with the nice distinction which Dr. Merritt makes between malocclusion and faulty occlusion. Malocclusion, or the improper relation between teeth in occlusion, and traumatic occlusion are undoubtedly the cause of a large majority of cases of pyorrhea. It is important that we recognize these etiological factors, for unless they are corrected, our work, however skilfully executed, will be haphazard and futile.

Dr. H. B. Matteossian. It has been a pleasure to listen to the very interesting and valuable paper presented this evening, covering all features of this disease—pyorrhea—which, like the poor, we have always with us, as completely in this single address as one could do within the limited scope of such a paper. There are many valuable points that the essayist has brought up, not the least of which is the emphasis laid on the necessity of a study of the anatomical construction of the parts. The free margin of the gums, being smooth and loose, not taut, is protected against the invasion of micro-organisms at the most vulnerable point of the gingiva. It defends itself against irritation: when the irritants are so strong and constant that the inflammatory reaction set up is inadequate to overcome them, the final pathological effects, which you have heard so graphically described, follow.

Another valuable point is the connection between certain diseases and pyorrhea, both as predisposing causes and sometimes as results. It is no exaggeration to say that pyorrhea "is not infrequently the indirect cause of these diseases," indeed it is often the direct cause. It may produce systemic infection that

may end fatally. There have been cases of enterocolitis, for example, caused by pyorrhea, where death has ensued, pyorrhea being the original disease, and the intestinal infection a sequel thereof.

Dr. Merritt has raised many points that might be discussed, but I shall limit myself to a few.

In connection with traumatic occlusion, which he has fittingly noted as an etiological factor, I should like to report briefly some observations I have made on the mouths of the people while traveling in Asia Minor. In an examination of six or seven hundred mouths, there was disclosed a peculiar condition, in that the atavistic attenuation of the alveolar process, so frequent in the western nations, was entirely absent. The teeth were beautifully formed, the jaws normal, the alveolar septum strong and well built; only two per cent. presented slight conditions of malocclusion. But, on the other hand, about sixty or seventy per cent., even of young people, presented pyorrhea, with large accumulations of tartar. The etiology of this was very interesting to study. I had a very short time in which to do this, but there were two observations that I made. One was with regard to the relation of heredity to the conditions found. There were signs of uric acid diathesis in these people. There was also, in nearly one hundred per cent., absence of the use of the toothbrush. Every one of these people exercised a very careful finger massage on the teeth and gums instead of using a brush. This shows the inadequacy of such treatment, and the great value of such energetic brush massage as the essayist has described, demonstrating the good results that are bound to ensue when the patient faithfully co-operates in preserving the health of the tissues after they are restored to normal.

A very interesting point is the question of reattachment. I confess to much curiosity, a frankly skeptical curiosity, as to proof of the bony nature of this reattachment. That tightening occurs we know, but that it is of a bony nature, we should like to see proved by radiographs or by sections. The alveolar process

is in its essence a transitory structure. Wherever there is a lesion of this structure, there is a tendency to excess of osteoclastic activity over osteoblastic. Hecker was the only one who presented a slide showing the regeneration of blood-vessels, making therefrom the farfetched deduction that bony regeneration would follow. Reattachment takes place, but we should be correct in ascribing it to fibroblastic activity.

The name "pyorrhea," as has frequently been repeated, is unfortunate. The name Talbot gave this disease during his admirable and fertile studies in this connection is much preferable.

There is another point regarding systemic diseases, that whereas they cannot be said to be directly causative of pyorrhea there is only one that simulates pyorrhea, and that is syphilis. There is a form of syphilitic manifestation in the gums which is a feature of that disease; it looks like pyorrhea, but is not. It is different in many ways, although there is a production of pus. There is blueness of the gum margin, due to venous stasis. Its relative intensity is often an indication of the comparative resistance of the individual, and the virulence of the infection. It is helped by the removal of local irritants. It is one of the manifestations of lues, not what we call pyorrhea, but a condition simulating it.

Dr. Alfred P. Lee. Dr. Merritt's definition of pyorrhea alveolaris as a disease is a logical one, viewed from both clinical and histological standpoints. I had hoped that he would go farther, and classify or present recognized types of the disease; for surely there are as many varieties of this affection, causing a wasting of tooth investment, as there are varieties of rheumatism or catarrh, or many other bodily ailments.

Do not misunderstand me as believing that the different forms of pyorrhea are necessarily due to a difference in the bacterial content of the so-called pyorrhea pocket, for I wholly agree with the essayist in believing that the organisms found in these pockets have no etiological relationship to the disease. They are entirely incidental and doubtless, as he

says, present not a qualitative, but a vast quantitative difference from those found in the normal mouth, due to the extremely favorable conditions offered by the presence of these pockets. This fact has proved, to me at least, that we have little to hope for in applying therapeutics to our line of treatment. We must rely upon surgery, elimination of faulty conditions, and restoration of normal conditions.

Clinical observations strongly incline me to the belief that there are several well-defined types of pyorrhea, and that these types are largely determined by predisposing causes. If this be true, then the name pyorrhea alveolaris is a most unfortunate one under which to group the whole family. Almost any one of the four or five other terms used would appear broader and more comprehensive.

The essayist's idea that a frail bony support is a contributing factor in this disease is one that interests me very much. This would seem to me to apply particularly to those cases in which an individual whose teeth are frailly supported is called upon to do the same work with his jaws as is the person whose teeth are more substantially supported. For instance, the soldier of small size is called upon to eat the same ration, and in the same length of time, as that given to his brother soldier, of giant frame. If this state of affairs were to continue over a long period of time, it is only mechanical sense to assume that the teeth of the frailer man would loosen, and their surrounding structures become diseased, before those of the man of massive frame would succumb. However, were it possible to give each of these men a ration and work corresponding to the thickness and density of the bony structure surrounding his teeth, this factor could be dismissed from our etiological studies.

I use and strongly advocate the method suggested by the essayist, of placing thin carbon paper between occluding teeth, in order to ascertain faulty occlusion that may result in trauma. Possibly no one thing in my own line of treatment has

produced more satisfactory results to the patient, and therefore to the operator, than this dressing down of high surfaces to prevent wound and shock to already irritated pericemental membranes.

Mouth hygiene, of course, plays an important part in successful pyorrhea treatment. How often, though, are we confronted with mouths in which the progress of the disease is notably rapid, although a mouth hygiene above the average has been regularly observed. On the other hand, a visit to our dental clinics will show cases in which the progress of pyorrhea is of slow character, although the toothbrush is a very occasional luxury.

There is no point in Dr. Merritt's paper that I wish to emphasize more than that where he says, "Another prolific cause of gingival irritation is faulty contact points." So many fillings are inserted with the apparent idea that if they "touch" the approximating tooth or filling, that is all that is to be desired. No attention is paid to the matter of placing the contact point exactly where nature intended it should be. Add to this the number of fillings that present flat surface contact to their neighbors and those that have no contact, and it is no wonder that we find these mouths with the gingivæ highly irritated and pockets established by food impaction. When it is just as easy to place the contact where it belongs, it is difficult to understand why so many men apparently go out of their way to place it elsewhere.

Also, there is no point in the essayist's paper upon which I wish to express more doubt than upon the statement that "reattachment takes place." That a "physiological contact between the vital cells at the cementum and the overlying soft tissues" may occur is highly probable, but I have yet to see demonstrated the reproduction of lost pericemental fibers. By re-establishing healthy conditions we get a hugging or adaptation of the tooth's remaining surrounding tissue; but I fear that the "new bone deposited about the roots," as claimed by Dr. Merritt, is of very slight degree. He says that "reattachment takes place, as

a rule, in the hands of the skilled periodontist." Evidently few of us have attained to that skill.

I trust that I am open to conviction, and I hope I am mistaken; but I have made, and yet make, the claim that the condition known as pyorrhea alveolaris (not a local gingivitis) is incurable. I so state to my patients, at the same time advising a line of treatment very similar to that advocated by Dr. Merritt; but I explain to them that any portion of the connecting membrane between the tooth and its socket, once lost, can never be replaced, although intensive treatment and watchfulness will reduce the progress of the wasting process to a minimum.

To revert to a statement made by the essayist in the earlier part of his very excellent paper: "As a rule, the progress of the disease is slow, often years elapsing between the initial gingival irritation and final exfoliation of the tooth," I would say that I feel that this exactly portrays the life-cycle of the pyorrhetic mouth. The question of *when* the patient loses his teeth so affected is simply a matter of months, years, or decades, depending upon many factors, not the least of which is the degree of surgical skill expended upon him by his dentist.

Dr. J. C. Curry. Dr. Merritt has made no statement in regard to the treatment of pyorrhea by splinting the teeth. I should like to know whether he has ever practiced that method in treating pyorrhea cases.

Dr. Doubleday. May I ask for one more explanation? That is, the differentiation between trauma and malocclusion. Where I have used the word trauma I have referred to the results of violence. Where there has been trauma to any extent, I have usually found pulp stones, particularly if there has been a great amount of trauma. I have used the word malocclusion to mean mechanical stress, coming from inclined planes, etc. I recall a case in which a woman, within two years, developed pulp stones in five teeth. Fillings had been removed, and the teeth had been restored by grinding the sulci and inserting inlays to open the bite. Out of five of the six teeth

thus treated I removed twenty-one pulp stones. She had suffered from insomnia to such an extent that she was unable to sleep more than an hour at a time for two years.

Dr. Merritt (closing the discussion). I have only a few words to say in closing. In the first place, I do not pretend to know it all. On the contrary, I know that I do not know much about pyorrhea, but I am interested in knowing more. I assume that you are also; and the best way to learn is to get together and exchange ideas, as we have done tonight.

There have been some questions asked that I shall not be able to answer. Many more might be asked to which the wisest of us could not reply. We all ought to know more about pyorrhea than we know, and if we did we would do better work for our patients than we are doing; and the only way in which we are going to accomplish this is by realizing our ignorance, and taking steps to correct it.

I myself realize that pyorrhea alveolaris is a very unsatisfactory term. In this paper I at first used the word periodontoclasia, but upon reflection I went back to the old term, because I did not want to confuse your minds by the introduction of a new word.

As to the relation of pyorrhea to systemic infection, I can only say that I do

not know. That it plays an important part there is no doubt, but just what it is, or just how it influences prognosis or acts as an exciting or predisposing cause, I do not know.

Now as to the question of reattachment: What the nature of it is, no one can say. There has never been a histological examination made of regenerated tissues of this kind. That they are the same as those tissues replaced I do not believe, but that they answer the purpose is true. That reattachment takes place there is no doubt, and if it does not in a given case it is because the conditions have not been met; it may be through faulty technique, or it may have been because of conditions which no human being could control. We are dealing with an environment constantly charged with organisms and food debris. When Dr. Lee tells his patients that pyorrhea is incurable, I believe he is doing them and the profession an injustice. Pyorrhea is a curable disease, though it may, through long neglect, reach an incurable stage. The sooner that this fact finds its way into the minds of the profession the better it will be for our patients.

A rising vote of thanks was given Dr. Merritt, and the meeting adjourned at 10.30 P.M.

THE DENTAL COSMOS

A MONTHLY RECORD OF DENTAL SCIENCE.

Devoted to the Interests of the Profession.

Subscriptions and communications relating to advertisements should be addressed to the BUSINESS MANAGER of the DENTAL COSMOS, Lock Box 1615, Philadelphia, Pa.

PHILADELPHIA, JULY 1918.

EDITORIAL DEPARTMENT

Oral Sepsis.

THERE has probably never appeared in medical or dental literature an article which has had a more profound influence on the thought and action of the medical and dental professions than the article by Sir William Hunter entitled "The Rôle of Sepsis and of Antisepsis in Medicine," which appeared in the *Lancet* for January 1911, and which we have republished at page 585 of the present issue.

It has been an invariable rule of the DENTAL COSMOS not to republish matter which has appeared elsewhere, but we feel that we are warranted in breaking this long-established rule in the present instance by the importance of the paper in question, and also the desirability from the historical standpoint of permanently recording this epoch-making address in strictly dental literature.

While there have been numerous references in dental literature to Dr. Hunter's paper, there are doubtless many in the profession who have never read the original address, but there is probably not a member of the profession whose methods of practice have not been materially affected as the result of the profound impression which Dr. Hunter's paper made upon both the medical and dental professions.

When the paper first appeared there was a wave of indignation and even resentment toward the severe indictment which Dr. Hunter made against certain practices in dentistry, and these practices were ably defended by many who were unwilling to accept such a wholesale condemnation of the methods of dental practice which were then in vogue; but no amount of argument could gainsay the evident truth of the soundness of the principles underlying Dr. Hunter's criticism of certain dental operative procedures.

At that time we presented an editorial dealing with the article in question, but our attention was focused more particularly on a review of the paper which was published in *Current Literature*, and which was a flagrant attempt at sensationalism and a palpable misinterpretation of the author's views.

Dr. Hunter was particularly severe in his criticism of crown and bridge work as practiced in European countries under the name of "American dentistry," a catch phrase which has long been used by incompetent charlatans throughout Europe in exploiting the ignorant and credulous, but which has no relation to the better type of dentistry as it is practiced in America. Many of Dr. Hunter's critics directed their defense of the then prevalent methods of practice at this particular phase of the article, which the reader will readily see is but incident to the broad question under consideration.

That Dr. Hunter's criticism of crown and bridge work as then practiced was well founded has been fully exemplified in the almost complete change in the methods practiced by present-day crown and bridge workers.

After the first wave of resentment against this criticism of our methods of practice had spent its force, it was soon recognized by the thinking members of the profession that the criticism, although a severe one, was just, and a calm and sober consideration of the question involved resulted in the awakening of the profes-

sion to the necessity of a proper consideration of the principles laid down by Dr. Hunter.

Truly it is an ill wind that blows no good, and one of the greatest goods that came from this epoch-making effort was the immediate and complete recognition which came from the medical profession of the potentiality for evil present in septic oral conditions—a contention which the dental profession had long endeavored to impress upon their medical brethren. Indeed, the medical profession recognized these potentialities for evil with such enthusiasm that we began to see medical men everywhere ascribing to mouth conditions almost every disease which they could not readily diagnose, and advocating, even urging, the indiscriminate extraction of teeth, and, as a matter of fact, this over-enthusiastic acceptance of oral sepsis and faulty dentistry as the possible cause of many puzzling conditions met with by the medical practitioner is not yet on the wane.

The most enthusiastic champions of dental hygiene as an important factor in general bodily health could not have hoped for such an overwhelming acceptance of all for which they had contended, but unfortunately this recognition of dentistry was entirely from the negative viewpoint of the baneful effects of improper dental practice. The medical profession as a whole has not yet conceded the contention of dentistry with regard to the beneficial results of proper methods of dental practice on the bodily health.

Some of the more thoughtful men of the medical profession, however, have come to realize what an important rôle preventive dentistry must play if we are to realize all that is hoped for from preventive medicine. Indeed, it was none other than Dr. Charles H. Mayo who said, "It is evident that the next great step in medical progress in the line of preventive medicine should be made by the dentists. The question is, Will they do it?" The dental profession has taken that step, and we feel confident in making the assertion that it has long since cast aside its septic swaddling-clothes.

One of the most beneficial results coming from this wholesale indictment of empirical dental practices by Dr. Hunter was the impetus given to research work and the study of dental conditions in their relationship to systemic diseases, until today the profes-

sion is wide awake to the fact that the mechanical aspect of dentistry, while an important one, can properly serve its purpose only when practiced with a full knowledge of the physiological functioning of the mouth as an important organ of the bodily economy. We believe also that this paper was the indirect source of considerable stimulus to the oral hygiene propaganda which has been so zealously promulgated by the dental profession in recent years.

We respectfully urge all our readers to study carefully Dr. Hunter's paper, and although it is some seven years since its first appearance, we feel that it is just as timely now as when it was originally published. We are still of the opinion as expressed in 1911 when we first made editorial reference to the paper in question: "While some of the statements made by Dr. Hunter are perhaps rather excessive, they are on the whole, we believe, in accordance with the general facts of the situation. Though the truth is frequently unpleasant, it is never unwholesome, and if the stimulus of Dr. Hunter's pointed criticism shall arouse the organized dental profession to renewed activity in the effort to eradicate the ignorant and incompetent practice of dentistry, he will have conferred a boon upon humanity." We believe now that Dr. Hunter's paper accomplished all and even more than we hoped for it at that time.

"l'Aide Confraternelle" Honor Roll.

In response to our appeal in the January issue we have received the following additional contributions to "l'Aide Confraternelle":

BIBLIOGRAPHICAL

ANATOMY AND HISTOLOGY OF THE MOUTH AND TEETH. By I. NORMAN BROOMELL, D.D.S., Professor of Dental Anatomy and Clinical Dentistry, Philadelphia Dental College, and formerly Dean and Professor of Prosthetic Dentistry, Dental Anatomy, and Histology, Dental Department, Medico-Chirurgical College of Philadelphia; and PHILIPP FISCHELIS, M.D., Associate Professor of Histology and Demonstrator in Embryology, Medico-Chirurgical College of Philadelphia. Fifth Edition, revised, with 368 illustrations. Price \$3.00. Philadelphia: P. Blakiston's Son & Co. 1917.

The first part of this well-known work, that dealing with the gross anatomy, has received some revision in regard to form and arrangement. The subject-content has not been altered. The osteology, myology, the vascular and nerve supply of the facial region receive the ordinary description to be found in any one of a number of the briefer works on human anatomy. The second part, that which deals with the histology, histogenesis, and embryology of the dental structures, has not been revised.

There are four most serious and salient adverse criticisms to be made of this work:

(1) The rather recent appreciation of the multiplicity of apical foramina, which has so deep a clinical significance, is apparently completely ignored; indeed, on pages 191 and 361 one is led to be-

lieve that each tooth has but a single apical foramen.

(2) The figures throughout the book are frequently too indistinct, and too often lack adequate correlation with the text descriptions. In the first part of the work, the figures illustrating the anatomy of the individual teeth should be made decidedly clearer and sharper, and larger, even at the sacrifice of some of the verbal description.

(3) It is unfortunate that the obsolete and anthropomorphic nomenclature of dental anatomy should be retained. There is no excuse for further delay in accepting the terminology which is in rational harmony with that of comparative anatomy.

(4) The periodontal ligament (misnamed by Broomell and Fischelis) is a structure of such high import to the dentist that it deserves a full discussion. The most serious error of judgment in the putting together of this book is that the student is referred "for full histological description" of this structure to a former edition. In the present (the fifth) edition there are devoted two pages, including one diagrammatic figure, to this topic.

In anticipation of a future revision of the second part of this book there are a number of items which would demand consideration. Nasmyth's membrane is described following the section on the dental pulp and preceding the section on "the alveolo-dental membrane." Logically it should immediately precede the

description of enamel. Contrary to the statement on page 361, lymphatics have been described in the pulp. (DENTAL COSMOS, 1917, p. 436.) Lacunæ are described as normal in the cementum, whereas there is excellent reason to believe that their occurrence there is an indication of a pathological process; the very description by the authors supports the latter view. The consideration of the innervation of the dentin needs amplification. In a subsequent edition it will be interesting to see how Bolk's views on human odontogenesis (DENTAL COSMOS, 1913, p. 1058) will be treated.

The defects and deficiencies of this book have been emphasized because much is expected of a work which has exerted and undoubtedly will exert a wide influence on the *personnel* of the dental profession. Under the guidance of a teacher of originality and resource, a class would gain from this book the basic information on dental anatomy and histology which is prerequisite for their future studies.

DENTAL AND ORAL RADIOGRAPHY. By JAMES DAVID MCCOY. Second Edition. Price \$2.50. St. Louis: C. V. Mosby Company, 1918.

The unqualified success of the first edition of this work amply justified the appearance of this second edition. The author has kept his attention focused on the beginner (and we must realize that all practitioners are as yet beginners in this highly important phase of dentistry).

The spirit of McCoy is that of unpretentiousness, a virtue all too sadly lacking in many modern dental publications. The book possesses that trinity of charms—brevity, simplicity, and clarity. In choice of terms the author is wisely conservative. He consciously avoids recog-

nition of such parvenus as radiolucency, radiopacity, etc.

Only in two particulars is one disappointed: one hunts in vain for any mention of stereoscopic radiographs in dentistry, and the crucial chapter—that on the Interpretation of Dental and Oral Radiograms—is far too short. This chapter is the “why” of the whole book, and yet it occupies only about one-twelfth of the text.

This book is needed by every dentist who employs radiography, and is still more urgently needed by those dentists who have not yet resorted to this indispensable adjunct.

A TEXTBOOK OF DENTAL HISTOLOGY AND EMBRYOLOGY, INCLUDING LABORATORY DIRECTIONS. By FREDERICK BOGUE NOYES, B.A., D.D.S. Professor of Histology, Northwestern University Dental School, 1896–1914; Professor of Histology and Orthodontia, College of Dentistry, University of Illinois, 1914. Second Edition, revised and enlarged. With 337 illustrations and 21 plates. Philadelphia and New York: Lea and Febiger, 1915. Price \$4.50.

The improved appearance, external and internal, of this book is the only significant change from the 1912 edition. The author has revised the illustrations in particular, and although the alterations have been slight, the publisher has ably co-operated, so that the pictures are very much more distinct than those of the first edition. Thirteen illustrations have been omitted, the book being thereby improved.

No attempt has been made to eliminate the rather serious errors of judgment of the first edition. Unnecessary and inappropriate sections still persist.

The purposes of the book would be more directly and forcibly realized (1) by restricting the attention to *dental* histology and embryology, and (2) by avoiding the flavor of provincialism, so justly criticized in the DENTAL COSMOS review of the first edition.

The abbreviation or omission of certain generalities of animal morphology (Chapters I, XXV, and XXVI, except the section on the Stomadeum, at the bottom of page 296, which could be incorporated with modifications in the following chapter), the elimination of those chapters (VI to XI, inclusive) which properly belong to a consideration of operative dentistry (although parts of these of histological import not contained elsewhere might be retained and inserted in other chapters), the omission of the chapter (XIX) on bone formation, and the omission of the chapter (XVI) on the pathology of the dental pulp, would free the book from the charge that it contained much matter not pertinent in a textbook on *dental* histology and embryology, and would emphasize those topics whose popularization it is the aim of the book to promote.

The charge of localism can be evidenced by a large number of details. One of these is that the space given to the epithelial rests within the periodontal ligament is out of all proportion to their histological importance, while their sinister potentiality which would justify this space, as constituting a *locus minoris resistentiæ*, is not considered. The discussion of the distribution of the nerves in the dental pulp in relation to the question of the sensitivity of the dentin is notably insufficient. It contains at page 177 the following quotation: "The most recent work upon this subject was done some ten or twelve years ago by Prof. Carl Huber," entirely ignoring

the work of Mummery, Dependorf, and Fritsch. This is merely one instance where the paucity of references to the literature indicates a lack of familiarity with the work of other men.

In addition to the two general criticisms which have been detailed above, the following miscellanies may be mentioned: Nasmyth's membrane apparently is considered of not sufficient importance to be mentioned. The soft tissues of the mouth (see Chapter XXIV) deserve a far more extensive description than they here receive. Tooth development (Chapter XXVII) and especially the histogenesis of the dental tissues, are all too cursorily treated. In a future edition it will be of interest to see what influence Bolk's observations will have had upon these subjects. The value of the book would be enhanced by a liberal expansion of the index.

In summary, the general impression created by a critical and sympathetic study of this book is that it was written not by a professional histologist, but by a man who is primarily a dental clinician.

ORAL SEPSIS IN ITS RELATIONSHIP TO SYSTEMIC DISEASE. By WILLIAM W. DUKE, M.D., Ph.B., Kansas City, Mo. Professor of Experimental Medicine in the University of Kansas School of Medicine; Professor in the Department of Medicine in Western Dental College; Visiting Physician to Christian Church Hospital; Consulting Physician to Kansas City General Hospital, Kansas City, Mo., and to St. Margaret's Hospital, Kansas City, Kansas. With 170 illustrations. St. Louis: C. V. Mosby Company, 1918. Price \$2.50.

The title of this little book makes one instinctively think of F. Billings' "Focal

Infection" (see DENTAL COSMOS, 1917, p. 927). Both works are equally valuable to him who would become conversant with this subject. Duke avows that "The main purpose of this volume has been to assemble facts which show, first of all, that dental sepsis is an extremely common condition, and second, that it may cause serious systemic disorders in many different ways."

The book is essentially a monograph "based upon an experience with more than 1000 carefully studied medical cases observed in a consulting-office practice." Hence much of the material is original, and is accessible nowhere else.

The historical introduction is an interesting reference to a few case histories of Benjamin Rush's. Unfortunately there is no attempt to present in due proportion and true perspective the history of the concept of oral foci of systemic infection. In spite of an admirable bibliography, there is no reference to Miller's epochal researches and conclusions, or to the early and original articles of Wm. Hunter.

Duke conscientiously recognizes the dental aspects of the problem, and enters into hearty co-operation with the dental practitioner. Nevertheless his discussion of the etiology and pathology of pyorrhea alveolaris is the poorest section of the book. Nowhere does he seem to realize the fundamental significance of that precocious senile alveolar atrophy signalized by Talbot, Hopewell-Smith, Maurice Roy, and many others, and clearly recognized even in 1778 by John Hunter

("Natural History of the Human Teeth," pt. 2, chap. 2). It was unnecessary in this chapter to refer to *Endamoeba gingivalis*; but if reference to it were to be made, it is absolutely inexcusable to imply priority in the study of this for Bass and Johns, and to ignore Smith and Barrett.

Duke does not accept Rosenow's contentions of the selective tissue affinities of the streptococci so unconditionally as does Billings. The former recognizes that these views are in no way necessary for the acceptance of the importance of oral foci of infection. An interesting phase of this question is the attention given by Duke to the influence of disease in other parts upon oral health and disease (*cf.* DENTAL COSMOS, 1918: L. M. S. Miner, p. 234, and W. Ashley Cooper, p. 530). The importance of this viewpoint has been entirely overshadowed by the volume of the evidence offered for the converse proposition.

The most novel part (Chapter VI) of Duke's monograph is the emphasis laid upon anaphylactic phenomena as a possible explanation of many systemic disturbances attributable ultimately to oral infectious foci. This view, while not entirely new (*cf.* DENTAL COSMOS, 1917: W. S. Hewitt, p. 43; N. P. Barnes, p. 353, and Wm. M. Wright, p. 354), still has never before received the recognition and elaboration we find in this book.

There are 170 illustrations, all well reproduced from roentgenograms of cases of dental infection. The mechanical make-up and appearance of the book are very satisfactory.

REVIEW OF CURRENT DENTAL LITERATURE

[*Lancet*, London, March 30, 1918.]

Non-union of War Fractures of the Mandible. BY PERCIVAL P. COLE.

The fundamental principle that shapes the procedure of what may be termed the "ideal" school is the restoration of the normal arch and the maintenance of accurate occlusion. In this spirit Cole has dealt with 270 cases. The total of ununited fractures numbers 30, an inclusive non-union percentage of approximately 11. Of these 30 cases union was in 12 absolutely hopeless, judged by no matter how exacting a standard. The resulting exclusive figure is approximately 7 per cent. These figures are ample justification of ideal aims. The ultimate and only test of a successful treatment of a jaw fracture should be a functional one—the patient's ability to masticate ordinary foods. Subjective must take precedence of objective signs. In general terms it may be stated that if both the masseters maintain attachment to the one fragment, disability is relatively slight.

A short summary of the methods employed to remedy these cases of non-union follows. *Plating* has a very small sphere of usefulness, owing to the fact that necessary contact cannot be secured without traction. In cases of old mal-union with considerable deformity the only possible method of dealing with the fragments may be to *wire* them immediately. Where wiring is practicable, success may reasonably be regarded as certain. Where *free autogenous bone-graft* has been resorted to, success is practically assured in at least 60 per cent. of cases. The results obtained by *pedicled grafts* are rapid and certain. To such an extent is this so that in cases of non-union amenable to this treatment success can be practically guaranteed.

Cole summarizes and concludes as follows: The results obtained by the operative treatment of non-union must be concisely summarized thus: Thirty cases have been sub-

jected to operation; in 2 cases the operation has been abandoned as impracticable. Of the remaining 28 cases, 10 have been operated on too recently to permit of any definite statement as to the results obtained. Of the 18 cases whose fate is known, 13 have been completely successful. 2 have been considerably improved, while the other 3 must be regarded as failures. Thus it will be seen that the percentage of success is over 70. There has been no mortality, and post-anesthetic complications have been entirely absent. In all but 2 cases ether has been administered by intratracheal insufflation. The results are such, in a word, as to justify the conclusion that no patient so afflicted should be discharged until operation has not only been offered to, but urged upon him. The functional disability associated with ununited fracture of the mandible is, in the vast majority of cases, an unnecessary disability.

[*Dental Items of Interest*, New York City, March 1918.]

Clasped Partial Dentures Versus Bridge Work. BY HART J. GOSLEE.

[*Dental Items of Interest*, New York City, February 1918.]

Mobile Bridges. BY L. GORMSEN.

The realization of the danger of local oral disease as a focus for systemic infection finds an expression in the renaissance of interest in prosthetic appliances. Never did the line between "plate work" and "bridge work" seem more arbitrary than it does today. The one requisite which is exacted of these types of restorations is that they be removable. This feature not only permits of thorough cleansing, but also allows the employment of retaining devices which do not necessitate the devitalization of healthy teeth. In this light the two articles given above become of great value.

In Goslee's opinion, the usefulness of fixed

bridge work scientifically adapted should be confined to small fixtures involving the replacement of one, two, three, or at most four teeth, and when the reconstructive and restorative requirements demand the replacement of more than this number, then some type of removable structure or partial denture is invariably indicated. As a means of differentiation between removable bridge work and partial removable dentures he submits that "partial removable dentures" include that type of fixture where the sustaining (retaining) support of the fixture is obtained only, or at least mainly, by means of contact with the contiguous soft tissues; and that where any form of attachment to either the crowns or roots of the remaining natural teeth is utilized, and acts as a means of retaining the fixture and of precluding any great degree of subsequent settlement of it, thus relieving the soft tissues of the entire responsibility of supporting the fixture, it may be properly classified as a "removable bridge," irrespective of whether the body be made of metal or vulcanite.

Whenever the position of the supporting teeth is favorable, two attachments will usually be all that will be required, though as the number of missing teeth to be supplied increases, and the position of the supporting teeth becomes more unfavorable, it may possibly become necessary to use three. More than two are rarely ever necessary, and only add to the difficulty of obtaining parallelism, and this in turn increases the strain thrown upon those so used.

When a concrete problem arises, and we must make decision of the fixture to be used, the first consideration incident to such selection is the inherent strength of the appliance. To secure this maximum of strength Goslee resorts to the use of "assembled abutments" or "alveolar bars." Abutment pieces in the form of gold or porcelain crowns may often be attached together with a 14-gage round iridio-platinum or clasp-metal wire lying just in contact with the immediate summit of the ridge. This method is especially useful when it is desirable or becomes necessary to use such naturally weak teeth or roots as third molars or second incisors, though it may be found useful when other teeth are involved, and in either arch, and more especially in those so-called "long span" cases where sev-

eral teeth are missing between those to be used for abutments.

Goslee's present purpose is to call attention mainly to, and to discuss but one particular form of the many removable attachments now in common use—the *clasp*.

Clasps have been much abused, but Goslee has seen many teeth supporting clasps in which the pulps were still alive after ten years, even though dental caries may have necessitated fillings.

The anatomy of the teeth indicates that clasps are mainly suitable for premolars and molars. The shapes of the crowns in the incisors and canines are usually not favorable to the grasping and self-engaging properties of clasps.

To be successful it is required that a clasp shall (1) possess both inherent strength and resilience; (2) be well adapted to the supporting tooth; (3) must encircle three angles of the circumference of the tooth in order to grasp it firmly and remain in correct position thereon; (4) must be provided with some form of *occlusal rest* as a means of minimizing abrasive influence and of precluding subsequent settling of the fixture, which would alter its position on the tooth and thus render the clasp useless or perhaps even injurious; (5) must not impinge upon the soft tissues or interfere with occlusion; and (6) it must be securely attached to the supporting structure. It is not clear what Goslee means by the last requirement. If he means the tooth by the "supporting structure," as seems most logical, then it is not obvious wherein this requirement differs from the second, third, and fourth. If by "supporting structure" he means the base of the prosthetic appliance, it is strange that he does not take exception, in the discussion which followed his paper, to the idea of movable clasps.

The occlusal rest is an essential part of a clasp in all cases and at all times. The type of clasp which Goslee has found to be most useful and least injurious to the supporting tooth is made in the form of a double loop of 17- or 18-gage round iridio-platinum or high-fusing clasp-metal wire. This wire is adapted and adjusted to a fusible metal model of the tooth. When this has been accomplished, the clasps are properly fitted in the mouth, and then, and not until then, the

full impression, with the clasps in position on the teeth, should be taken in plaster, and the model made. Thus the original model will have the clasps, the form and shape of which are not to be subsequently altered, in position upon it. The base of the denture may now be made in metal or vulcanite. The attachment of the clasp to the base is an extremely important consideration, and must be done so as to secure adequate strength, and at the same time permit of an unrestricted freedom in the springiness of both ends of the clasp.

The discussion which followed the reading of Goslee's paper is thoroughly practical. It is particularly interesting because it developed a subject which has not as yet received general recognition, viz, the desirability of allowing some freedom of motion between the prosthetic appliance on the one hand and the abutment on the other. Norman Essig described a considerable number of movable clasps, designed to accomplish this purpose. His technique cannot be abbreviated, and should be consulted in the original, where clear drawings facilitate one's grasping his ideas. Ottolengui described a movable clasp, which is attached to the base by means of an oval upright post and an oval tube, in place of the round upright post and round tube mentioned by Essig. The oval nature of the post and tube permits sufficient play without allowing the clasps to get out of alignment when removing and replacing the piece.

The central thought of Gormsen's paper is the desirability of allowing some freedom of motion between the prosthetic appliance and the abutment.

He introduces the term *mobile* bridges, because it expresses the thought that bridges should have a certain mobility, so that their abutments may not be strained more than is absolutely necessary. He emphasizes that mobile, not merely removable bridge work, is in every case to be preferred to fixed work. Gormsen's appliances are not to be mobile to the extent that their mobility is noticeable to the patient, or that the bridge should fall off. At this time we can note that partial dentures well meet this requirement of mobility.

Most of the existing systems for removable bridges can readily be adapted to meet Gorm-

sen's requirement. He personally is attached to Peeso's method. In this form of bridge, the mobility can easily be produced when the bridge is finished, by grinding or polishing the telescope caps and split pins so much that they become very loose, so loose that when one has the inner cap of the telescope crown in the bridge, it can be pushed off with a touch of the hand. It is absolutely essential that the abutments be exactly parallel, otherwise the desired mobility cannot be obtained. Gormsen believes that by his method one can make use of abutments which ordinarily would be considered too weak to bear their load. This principle he illustrates by reference to cases in practice.

Note upon Mottled Teeth. BY PIERGILI.

This note was called forth by the elaborate studies of Black and McKay in the *DENTAL COSMOS* for February, May, June, July, and August 1916. To these authors the etiology apparently was most obscure, although there was some evidence that there was some correlation, more than pure coincidence, between the pathological condition and the drinking-water supply.

Piergili quite positively advances his views. The qualitative chemical analysis of the water gives no result, but the quantitative analysis has revealed a common characteristic in the waters of the regions wherein this dental lesion is endemic; a minimum content of mineral salts in general, and of the salts of calcium in particular. This minimum content of calcium salts is the cause of the condition which produces mottled teeth. Chemically, water with its dissolved carbon dioxide has affinity for calcium carbonate. Unless this affinity be satisfied before the water be taken into the mouth, it will (unless the teeth have reached a certain maturity of hardness) dissolve out from the teeth this latter salt.

An Investigation of the Methods of Disinfection Carried Out in Dental Offices. BY ADAH ROBERTA HOLMES.

This extensive and voluminous report comprises one of the most valuable contributions to the subject. The objects of the author

were (1) to point out the dangers of careless methods of disinfection; (2) to demonstrate positively that such methods are at present practiced by many of the profession, and hence the pressing need for their remedy; and (3) when in any way possible, to recommend a standard inexpensive and efficient technique for dental offices.

In reality the paper is an elaborate compilation of data furnished by seventy questionnaires, supplemented to a relatively small extent by personal visits to dental offices. The first two objects may be accepted as unquestionably attained, although some of the remarks would lead one to conclude that the writer is more or less unfamiliar with the exigencies of dental practice. The third object, which is urgently needed, is left for report at some future time. This must be waited for with great interest. We must not forget that such a ponderous, laborious, and minute statement as this present report is of great worth as a logical and necessary prerequisite to the future report, of immediately practical bearing, on the standardization of an inexpensive and efficient technique for dental offices.

On Bone-Grafting in Gunshot Wounds of the Mandible. BY HARRY PLATT, GEORGE G. CAMPION, AND BARRON J. RODWAY.

During the past two years more than 500 cases of injuries of the lower jaw have been under treatment in the hospital at which the authors are stationed. The operation of bone-grafting has been performed nine times out of this number. They have found that two distinct types of fracture exist in which the autogenous bone-graft can be used—(a) where there has been a considerable loss of bony tissue with a resulting gap, and (b) where with comparatively close apposition of the fragments an unstable fibrous union has developed in spite of long-continued fixation by splints. In (a) the function of the graft is to restore continuity; in (b) to bridge over the small gap entailed in any refreshing operation (a refreshing of the healed bone ends). The authors briefly describe eight of their cases. They used grafts from rib, scapula, and tibia, preferring the rib. In fixing the graft, they carefully avoided all foreign materials. Where it has been possible they

maintained immobility by splintage for some time after the operation. The Claude Martin flange-splint has proved of great value, especially where the smaller fragment is edentulous. The 11 roentgenograms which accompany this article demonstrate the mechanical and physiological functions of the graft.

The Treatment of Cancer of the Lip by Radium: A Report of Twenty-four Cases. BY HENRY H. JANEWAY.

This brief summary, the result of much work, is both concise and convincing. Epithelioma of the lip offers favorable conditions for successful treatment, whether by operation or by radium, more frequently than the majority of other forms of epidermoid carcinoma. The reason for this is, not because of less malignant tendencies, but rather because of the exposed position of cancer of the lip. Janeway concludes that the degree of success obtained in the treatment of operable cancer of the lip by radium in the series of cases here reported, and the maintenance to date with such regularity of the healed condition in the earlier cases treated, justifies a continuation of the use of radium in operable cancer of the lip. He recommends the application of radium emanation embedded in molds of dental compound, and filtered through the thinnest material, for the most superficial lesions. The use of emanation instead of radium element facilitates uniform distribution over the lesion, and provision for uniform distribution is the most important factor in obtaining a successful result. The superior adaptability of radium emanation for the treatment of cancer makes the use of the element itself obsolete, and for the vast majority of cancers it is inefficient.

Ionization Applied to the Treatment of Facial Cicatrices. BY HOLLANDE.

Hollande employs a constant current of 220 volts. The strength of the current should be very weak—10 m.a. The passage of the solution of the electrolyte produces its effect upon the cicatricial tissues in proportion to the weakness of the current. He uses potassium

iodid (KI) 1 part in 100 parts of distilled water.

The electrode is generally 5 by 4 cm. Nevertheless its dimension varies according to the extent of the scar. For the face, the electrodes are very near each other. The negative pole is placed upon the cicatrix to be treated; the positive pole, being the farthest, is generally placed under the chin. The positive pole is saturated with the solution of KI. The sittings are given every day for 20 to 25 minutes, during three weeks at least, or about a month. However, in the case of obstinate cicatrices, it may be necessary to prolong this treatment during many months before obtaining appreciable results.

Hollande gives the following conclusions:

- (1) The influence of KI plays a certain rôle in the softening of cicatricial tissue; the scar progressively loses its peculiar characters—color, stiffness, and adherence—and consequently permits the play of the underlying muscles; the circulation resumes its course.
- (2) Adherence to osseous tissue disappears as well as the trophic disturbances.
- (3) Ionization renders a real service to the surgeon for the repair of scars already freed from the subjacent tissues.

[*American Journal of Surgery*, April 1918.

Quarterly Supplement of Anesthesia and Analgesia.]

Changes Produced in the Blood by Nitrous Oxid-Oxygen Anesthesia. BY THEODORE D. CASTO.

This is an extension of the researches reported in the *DENTAL COSMOS*, vol. lvii, 1915, p. 881; also vol. lix, 1917, p. 415. The animals used in the present series of experiments were albino rats (*Mus norvegicus*, var. *albinus*). The erythrocytes were decreased in number after anesthetization with nitrous oxid and oxygen for from thirty minutes to one hour, the maximum decrease in the twenty animals studied being 70 per cent., the minimum 1 per cent., with an average of 25 per cent. The leucocytes did not show any change in actual number that was constant throughout the series of experiments. A differential count, however, showed a marked tendency on the part of the poly-

morphonuclear neutrophiles to decrease and of the lymphocytes to increase. The hydrogen-ion concentration of the blood was slightly greater in anesthesia than under normal conditions. The alkali reserve of the blood was depleted during anesthesia. This decrease was comparable to that of a mild acidosis in man. Histological preparations were made to determine the rôle of the spleen in the blood changes under anesthesia. In general, it may be said that no evidence was developed to show any profound or even slight pathological conditions existing. There appear to be no radical changes which take place in the tissue of the splenic pulps, the cells, nor in the Malpighian corpuscles of the spleens of those rats which were given a continuous dose of nitrous oxid-oxygen until death supervened.

[*Lancet*, London, April 13, 1918.]

Unilateral Hypertrophy of the Mandible. BY H. P. PICKERILL.

Pickerill has had 3 cases of (apparent) unilateral hypertrophy of the mandible resulting from gunshot wounds. In all 3 cases the injury has been a small piece of shrapnel (about the size of a pea) lodged in the pterygo-maxillary fossa. In none of these cases has there been any sign whatever of infection—the wounds have healed by "first intention." There has been no pain, no paralysis, no anesthesia, no fracture, practically no loss of function, and X-ray examination has in each case been negative. Yet in each case there has been an obviously increasing asymmetry of the face, the chin deviated away from the side of the lesion, and there was marked bulging both above and below the zygoma. The only "positive" sign has been a slight hyperemia of the side of the lesion. Pickerill attributes the asymmetry to vasomotor disturbance due to injury in the pterygo-maxillary fossa, and in one of the cases there was evidence of a deep hematoma due to wounding of the internal maxillary artery.

This note was called forth by a case of the same title recorded by William Edmond in the March 30, 1918, *Lancet*. In Edmond's case there was no history of injury, and the pathogenesis was entirely obscure.

PERISCOPE

Matrix.—A celluloid strip cut to shape, with two holes punched at the ends, and held in place by the ivory matrix retainer, makes a very good substitute for the metal band. One has the advantage of watching the cervical margin also.—R. MCCLINTON, *Commonwealth Dental Review*.

To Remove Mercury Stain From Gold Crown.—If you chance to have your gold crown or bridge discolored by coming in contact with mercury before being cemented to place, heat it to drive off the mercury, and, if necessary, restore the polish with your finest abrasive.—O. V. CALKINS, *Dental Review*.

After-pain Following Operation.—There is one preparation which will give great satisfaction, and that is a solution of guaiacyl and glycerin. This has been found to be the best preparation for the relief of pain. Orthoform is of service also, but guaiacyl and glycerin in equal parts is an almost unfailing agent for the prevention of after-pain.—L. M. S. MINER, *Journ. N. D. A.*

Die and Counter-die for Swaging Saddles.—After making an impression, take Melotte's moldine, place it around where you want your saddles, and flow it up with Melotte's metal, thereby working your counter-die first; repeat the process with your moldine and make your die in the same manner. Allow this to cool and your gold saddle can be swaged out immediately.—Minneapolis District Dental Journal.

Bismuth-Iodoform-Paraffin Paste.—Bismuth-iodoform-paraffin paste, or "bipp," as it is called, has now many advocates. Its use in wound treatment has spread considerably during the year. The paste consists of bismuth subnitrate 1 part, iodoform 2 parts, liquid paraffin 1 part, and it is applied freely to the wound, which is entirely filled with the paste and dressed, with sterile gauze. In preparing "bipp" great care must be taken to insure freedom from grit.—*Amer. Journ. of Pharmacy*.

Lysol.—Lysol is a brown, oily looking, clear liquid, with a creasote-like odor. It is made by dissolving the fraction of tar oil which boils between 190° C. and 200° C. in fat, and subsequent saponifying by the addition of alkali in the presence of alcohol. It contains 50 per cent. cresol, is miscible in water, forming a clear, frothy liquid. It is a more powerful germicide than phenol.—ADAIR ROBERTA HOLMES, *Journ. Calif. State Dental Association*.

To Desensitize Teeth that Are Sensitive to Scaling.—Dry the sensitive part thoroughly. Apply for four or five minutes a hot saturated solution of potassium carbonate in glycerin on a pellet of cotton. Dry the part with warm air. Repeat the application, leaving the cotton in place until the patient notices a burning sensation in the tooth, when the scaling may be continued painlessly. This solution will not cause discoloration.—A. DE VRIES, *Dental Review*.

To Clean a Blocked Hypodermic Needle.—To unblock long hypodermic needles, screw the needles on the syringe tightly, put distilled water in the barrel, hold the needle in the flame, and apply pressure with the piston. Steam is thus created in the immediate vicinity of the flame, which exerts pressure sufficient to unblock the needle. Bear in mind that passing through the flame removes the temper, and care should be taken in its use.—H. M. HALPERON, *Dental Review*.

Large Amalgam Fillings in Doubtful Teeth.—Sometimes it is expedient to provide for the possibility of having to remove the filling to obtain re-access to canals, and yet to provide a hard filling, or at any rate a filling hard on the surface. The difficulty is met by filling the bulk of the cavity with an amalgam in which tin predominates, and covering with an amalgam in which silver predominates. This filling will be as useful as an all-hard filling, but if it has to be removed it will be easy to do so after having cut through the casing of hard amalgam.—HUGH PATERSON, *Commonwealth Dental Review*.

Centrifugal Casting.—After about eight years' experience with various forms of casting apparatus, I have come to the following conclusions: (1) That the casting process is invaluable in the case of inlays, crowns, or anything resting on a hard surface which does not yield to pressure; (2) it is of distinct value in difficult lowers; (3) a swaged plate is best in the average upper case; it is more resilient, stronger, and takes a higher finish.

All the different forms of casting apparatus will give good results. The centrifugal force, acting as it does simultaneously on every atom of the molten metal and drawing it into the cast, seems ideal in theory; in practice, however, the other methods give equal results.—COLIN KEAY, *Brit. Dental Journal*.

Casting Dummies for Bridge Work.—

It is rather difficult to carve a wax pattern for a dummy, and also extravagant to use 24-k. gold in order to get a solid gold tooth that will not discolor in the mouth. My method to overcome these two points is as follows: Select a facing or porcelain tooth the exact shape and size required to fill the space. Run a die and counter-die in Melotte's metal, using the selected porcelain tooth as a pattern, and strike up a shell with 24-k. or sovereign gold. Trim this shell to fit the model. Now solder a small clip as a retaining point inside the shell and fill with wax; replace on the model, and carve away all surplus wax. Place a sprue into the thickest part of the wax, invest, and cast with scrap or inferior quality gold. This will give a solid dummy, and one which will not discolor where exposed to view.—*Commonwealth Dental Review*.

Unsterilized Root-canal Instruments.—

It is almost inconceivable that for years dentists, dental surgeons, if you please, should have strayed so far from basic principles that they should overlook the danger of plunging a barbed broach into a vital pulp unless that broach has previously been sterilized. The same thing applies to all other instruments used in root-canal operations, and yet you and I know that up to within the past four or five years sterilization of our fine root-canal instruments was not a process in general use. These instruments may be sterilized in various ways. One simple method is by employing the Halverson sterilizer. Have the water boiling; the instruments, on a small tray which comes with the sterilizer, are put in the water, and from there are

placed in the warm air chamber, and quickly dried.—ELMER S. BEST, *Minneapolis District Dental Journal*.

Making a Plate Prior to Extraction.—

I saw something in your "Hints" column about making plates before extractions. I have taken an impression for an upper, and cut off five fronts and three bicuspid on the plaster model, and made the vulcanite plate with the eight teeth on, then extracted the teeth and put the plate in right away, and the patient was very pleased.

I find it a good plan when there are many teeth to extract and the patient has not worn a plate, to extract the bicuspid and molars, make a plate with the posterior teeth, and let the patient wear it for a few weeks; then take an impression with the plate in, cut off the plaster fronts and add to the plate before extracting the anteriors, and let the patient use it as a temporary plate until the gums shrink. This acts well with a lower plate also.—C. PATERSON, *Commonwealth Dental Review*.

Advantages of Phenol-sulfonic Acid.—

The consistence of this agent is thick and syrupy, rather oleaginous in character, in the 80 per cent. strength which is recommended; thus a drop will adhere to the end of a broach or other applicator, permitting it to be carried even into the canals of upper teeth without difficulty. The acid does not materially affect a broach, and if any of it accidentally gets on the enamel of the crown of the tooth and is not noticed for a time, it does not decalcify and whiten the spot to the extent that sulfuric acid would do. When the acid is worked through the end of the root, as is desirable for cauterization in cases of a dental granuloma or alveolar abscess, it is sufficiently cauterant for the purpose desired, yet not as destructive as sulfuric acid would be, and owing to its analgesic tendencies it causes less pericementitis. In this connection, however, I want to say that we should not expect to do this work as it must be done, without more or less soreness following the treatment. There is a wide variance in patients regarding the reaction of the periapical tissue to these agents, and in these chronic conditions it is generally best to invite and create inflammatory reaction, that the sluggish cells in the area may take on new life and activity. This should not be done, however, at the expense of unnecessary destruction of tissue.—J. P. BUCKLEY, *Journ. N. D. A.*

Anilin Dye as a Germicide.—The following method of preparation and application has been used with much success in my practice for the past year, in treating chronic abscess and pyorrhea. Make a solution in the proportion of about half a grain of anilin violet (methyl-violet B) to one dram of distilled water. Inject a small quantity of the solution into the fistulous opening of the abscess, with a blunt-pointed syringe. The syringe should have a glass barrel, and the point be of either gold or platinum. The abscess should be treated surgically first. If necessary it should be curetted, or in a case of root-excision the parts should first be properly cared for. The anilin solution should be used three or four times at intervals of every other day. It may be applied with cotton twisted on a broach. In severe chronic cases or in pyorrhea pockets a small pledget of cotton may be saturated and pressed into the orifice and left for twenty-four hours. The anilin treatment may be followed with bismuth paste as a final dressing. In using anilin dye it is necessary to use some care on account only of the color, as there is absolutely no danger from the stain on the lips or tongue. Besides, the stain can readily be removed with absorbent cotton and water.—GEO. D. SITHERWOOD, *Dental Review*.

Sterilization of Instruments.—The problem before dentists at the present time in the transmission of disease-producing organisms is the same great problem that has been so well attacked and overcome in general surgery against wound infections since the revolutionary teachings of Lister. Surgeons have been forced to improve their methods from the fact that an infected instrument introduced into a wound or the field of operation produces an infection which has frequently been traced directly to the use of such unsterile instruments or faulty technique. On the other hand, when a patient receives the causative agent of disease from an unclean dental instrument, he does not know the disease was acquired in this manner; the dentist does not know it, in fact probably does not even know of the presence of the disease-producing organisms. There is no way of absolutely tracing infections contracted in a dental office; therefore, for his carelessness the accusing hand does not always point directly at the dentist as with the surgeon.

The knowledge of asepsis in surgery, and of bacteriological expert laboratory controls, must be the spur to advance along these lines, and so there must be developed in each one an antiseptic technique, and an "antiseptic

conscience."—ADAH ROBERTA HOLMES, *Journ. Calif. State Dental Association*.

Removal of Thirty Denticles From One Bicuspid Socket.—On May 29, 1917, a woman, age twenty-three, called my attention to a slight prominence of the gum buccally

FIG. 1.

Collection of denticles in upper right bicuspid region.

FIG. 2.

The thirty denticles removed from the bicuspid socket.

to the upper right bicuspid region, which had not produced any symptoms other than the elevation of the tissue.

Fig. 1 is a roentgenogram of the upper right bicuspid region showing the presence of a collection of denticles. The patient was referred to Dr. John Voss of Iowa City, Iowa, who extracted thirty denticles (shown in Fig. 2) from the first bicuspid socket. All teeth were present, and occlusion was perfect, excepting the third molars, which had not erupted.—BUNDY ALLEN, M.D., *Journ. A. M. A.*

Treatment of Oral Sepsis.—In my opinion, the original focus of the severer types of oral sepsis is at the margin of the gums and teeth. Mastication forces food in between the teeth, and between the gums and teeth. This food sets up a certain amount of irritation, and forms a suitable nidus for various organisms. The first problem is how to prevent food lodging in these sites; this can be solved only by efficient cleansing with a brush, which must be fairly stiff, and used after each meal in conjunction with a powder. I have found the following excellent: Magnesiae carb. pond. 3 parts; sulf. sublim., sapo castil., aa 1 part; ol. menth. pip. q. s. If gingivitis or pyorrhea has already commenced, the affected area should be firmly swabbed with a small, tightly rolled pledget of wool held in a pincet and dipped in liq. cresol saponis or any of its substitutes, taking care to remove the excess before using. A tumbler of warm water and spittoon should be ready to use immediately after. The thymol mouthwash should be prescribed. This method, I venture to predict, will come as a revelation to all who have labored for weeks and months with iodine, hydrogen dioxid, and other methods, as it is so rapid in its effects; only in very advanced cases have I found it necessary to apply the liq. cresol saponis twice, and rarely three times, at two-day intervals.—N. C. FISCHER, *Brit. Journ. Dental Science*.

Paraffin Treatment of Burns.—The use of a French proprietary called ambrine was announced comparatively early in the war. Ambrine is a preparation of hard paraffin, containing, some say, resin and oil of amber. When melted and applied to burns or wounds, it forms an airtight coating, under which the lesion rapidly and completely heals. Its success was undoubted, and it was not long before investigations were afoot with a view to ascertain the rationale of its action, and if possible, to discover an effective and inexpensive substitute for use on a large scale. Ordinary paraffin was not sufficiently plastic when applied to the skin, and attempts to mix resin with it failed, owing to separation of the resin when the mixture was heated. It was found, however, that when hard paraffin was heated to 130° C. by means of superheated steam, some molecular change took place. The melting-point was reduced sev-

eral degrees, and the substance took on properties similar to ambrine. This paraffin, with the addition of certain antiseptics, is known officially as "No. 7 Paraffin," and its formula is—Resorcin, 1 part (or beta-naphthol, 0.25): oil of eucalyptus, 2; olive oil, 5; hard paraffin, 67; soft paraffin, 25. The method of application is as follows: The burn is washed with sterile water, and carefully dried; a layer of melted paraffin is then painted on, and covered with a thin layer of cotton; a second layer of melted paraffin is applied over that, and the whole covered with wool and a bandage. The dressing is changed daily at first, later every second day.—*Amer. Journ. of Pharmacy*.

A New Thought About Making Plaster Models.—Making plaster models that are exact and perfect duplicates of the parts involved, and at the same time strong and substantial, with the thin ends and angles of the teeth reproduced absolutely perfectly and of sufficient strength, and securing a model of isolated teeth standing alone at some distance from neighboring teeth, with such strength that they will not break off from the model when separating, or subsequently while working on the case, is often fraught with sore trials and disappointments, because dental plaster does not possess the desired edge and angle strength, nor sufficient strength to sustain a model of a slender tooth standing alone in many cases. The following described method will enable you to make a model possessing all the desired qualifications suggested above: Before filling the impression with plaster fill the portions of the impression in which you desire strength and accuracy with synthetic porcelain, or Aschers artificial enamel, or a good quality of dental cement, and while it is soft and plastic insert a piece of copper wire or staple of the required gage to give strength, leaving the staples protruding from the porcelain, enamel, or cement, whichever you use. When hardened fill up the impression with plaster so that the protruding staples will be embedded in the plaster, thus holding all parts of the model firmly together. Upon separating the case you will find the thin edges and angles of the teeth perfectly reproduced and strong, and the isolated teeth of the model firm and strong also.—H. A. CROSS, *Dental Review*.

OBITUARY

Dr. Alvin Richard Eaton.

[SEE FRONTISPICE.]

DIED, Tuesday, April 9, 1918, in his seventy-ninth year, at his home in Elizabeth, N. J., after an illness of several months, ALVIN RICHARD EATON, D.D.S.

Dr. Eaton, the son of Edwin D. and Harriott (Litchfield) Eaton, was born in Whitehall, N. Y., March 19, 1840, where he received his preliminary education in the public schools of that city, later attending the Columbia Grammar School in New York and a private academy at Keyport, N. Y.

While still a young man, Dr. Eaton removed to MacGregor, Iowa, in which place he was engaged in business for a number of years. In 1862 Dr. Eaton returned to the East, and having determined to take up the study of dentistry, entered the office of Dr. Pretere. After completing his studies under Dr. Pretere, he returned to Whitehall, N. Y., and there began the practice of dentistry.

In 1872 Dr. Eaton removed to Elizabeth, N. J., and associated himself with the late Dr. A. W. Kingsley, which partnership continued until Dr. Kingsley retired, after which Dr. Eaton continued the practice thus established until February 1917, when he also retired from active practice. In 1888 Dr. Eaton entered the Baltimore College of Dental Surgery, from which institution he received his D.D.S. degree.

Dr. Eaton was a charter member of the Dental Society of the State of New York; a member of the New Jersey State Dental Society, serving as its president in 1886; a member of the Central Dental Association of Northern New Jersey, and also served as president of this society in 1890; an associate member of the New York Institute of Stomatology; member of the American Academy of Dental Surgery of New Jersey, serving as its

treasurer in 1886; a member of the New York Odontological Society; was first president of the New Jersey State Board of Registration and Examination, of which he was a member for many years, and in the work of which he took an enthusiastic interest.

Dr. Eaton was largely instrumental in founding the Free Dental Clinic for school children in New Jersey, and was the treasurer of the free dental clinic of Elizabeth until the time of his retirement from active practice.

Dr. Eaton was a member of the Masonic Lodge of Whitehall, N. Y. He was the first president of the Suburban Club of Elizabeth and also a member of the Mattano Club and the Elizabeth Club as well as of the Elizabeth Town and Country Club. He was a member and communicant of St. John's Episcopal Church of Elizabeth.

On the occasion of the fiftieth anniversary of his entrance into the practice of dentistry, March 18, 1911, the Dental Society of the State of New York and the New Jersey Dental Society tendered to Dr. Eaton a complimentary dinner at the New York Athletic Club, New York City. On this occasion Dr. C. S. Hardy, a lifelong friend of Dr. Eaton, paid to him the following tribute:

This dinner is given to our guest, not only that we may in this way pay tribute to his seventy-first birthday and the beginning of his fiftieth year of practice, but to show our appreciation of the high quality of work he has done through these his many years of labor as a practical dentist. To pay homage to the stalwart figure of more than threescore and ten that contains such a noble man, retiring and unostentatious, yet a man among men, bearing malice toward none and with charity to all; who has reaped his harvest, and blended harmoniously his own atmosphere—who has sown the seeds of kindness and

encouragement, alike amid adversity and prosperity, and like the weathered oak has stood the test of time and gale, thus individually increasing the flow of that eternal stream of progress which by its gradual refinement has added to the world's culture and enterprise.

Such men we should all emulate. The power of his example will live long, and its influence will be felt beyond a generation—fortunate indeed are those who can so pattern after him.

Dr. Eaton was married on June 29, 1863, to Miss Katharine Jane O'Reilly of Whitehall, N. Y. Dr. Eaton is survived by two sons, Capt. Robert L. Eaton and Dr. Alvin R. Eaton, Jr., of this city.

THE members of the Union County Dental Society wish publicly to express their sorrow at the death of their friend and associate, Dr. Alvin R. Eaton of Elizabeth, N. J., and to that end have passed the following resolutions:

RESOLVED, That in his death we feel the loss of a valued and esteemed member, who always stood for the highest there is in dentistry; and be it

RESOLVED, That the warmest sympathy be extended to his family in their great bereavement; and be it further

RESOLVED, That a copy of these resolutions be spread upon the minutes of this society, and that a copy be sent to the various dental journals.

A. P. ROBERTS.
OSCAR ADELBERG,
Committee.

Dr. Rufus W. Carroll.

DIED, Friday, April 26, 1918, at his home in Beaumont, Texas, at his fifty-third year, RUFUS W. CARROLL, D.D.S.

In the death of Dr. Carroll his community and state lost a good citizen and the dental profession a man of sterling qualities, who ever upheld its highest traditions.

Dr. Carroll was born in Natchitoches Parish, La., in 1865. He came to Texas in 1883, and was actively engaged in the prac-

tice of his profession in Beaumont for thirty years.

After graduating from Baylor University at Waco, Texas, Dr. Carroll entered the Dental Department of Vanderbilt University, Nashville, Tenn., where he received the dental degree in 1888. In that same year he was married to Miss Lutie Banks Armstrong of Nashville, Tenn.

Dr. Carroll was a member of the Texas Dental Society, the National Dental Association, and of the old Southern Dental Association until it merged with the National. He was an active worker and served on many committees. For a number of years he was chairman of the board of censors of his state society, of which at the time of his death he was first vice-president. He was a member of the Woodmen of the World, and of the First Baptist Church of Beaumont.

During his long practice in Beaumont, Dr. Carroll by his exemplary life and earnest work gathered about him a host of friends, and his death caused sorrow in many homes in Jefferson county, as well as in other sections where he was known.

Dr. Carroll is survived by his wife and six children.

J. E. STOREY.

"In Memoriam" Resolutions.

Dr. Isaac H. Davis.

THE following *in memoriam* resolutions on the death of Dr. I. H. Davis were adopted by the Maryland State Dental Association at its February 1918 meeting:

Whereas, an all-wise Providence in His infinite wisdom has taken from our midst through death one of our highly esteemed and well-beloved members, Dr. Isaac H. Davis; and

Whereas, his life, work, and association have been an example and stimulus to the many who knew him well and were privileged to come under his influence; and

Whereas, his usefulness as a citizen, teacher, practitioner, and member of this body

has ever been strikingly commendable in every respect; therefore be it

RESOLVED, by the Maryland State Dental Association, that its membership keenly feels the loss sustained through his demise, and hereby gives expression to its sincere sympathy with his family in their period of sadness; and be it further

RESOLVED, That we, individually and collectively, heartily attest to his nobility of character, his ideal life, his professional skill and peculiar tactfulness, his gentle and cheerful spirit, his bighearted and genuine interest in human uplift, which qualities deservedly endeared him to a multitude of friends; and be it further

RESOLVED, That by the death of Isaac H. Davis the state has lost a valuable citizen, the school with which he was long associated a successful and conscientious teacher, the profession of dentistry an energetic, ethical, and worthy representative, and this body a devoted, loyal, and helpful member; and be it further

RESOLVED, That a copy of these resolutions be forwarded to his widow.

F. F. DREW, *Corr. Sec'y.*

Dr. John H. London.

THE following resolutions upon the death of Dr. John H. London were adopted by the District of Columbia Dental Society, March 19, 1918.

Whereas, the Supreme Master in His wisdom has seen fit to remove from us Dr. John H. London, for many years an esteemed member of his chosen profession, it is fitting that we should make a record of his death, and express our sorrow over the untimely close of his career; and

Whereas, his exceptional interest in his profession and his beautiful character endeared him and made him lovable to all who knew him; therefore be it

RESOLVED, That we, the members of the District of Columbia Dental Society, feeling deeply our loss, hereby express our appreciation of his friendship; and be it further

RESOLVED, That these resolutions be spread upon the minutes of the society, published in the DENTAL COSMOS, and that a copy be sent to the widow.

CHESTER A. BAKER,
THOS. L. RUST,
ALLAN S. WOLFE,
Committee.

DENTAL COLLEGE COMMENCEMENTS

University of Pittsburgh School of Dentistry.

THE annual commencement exercises of the University of Pittsburgh, School of dentistry, were held in Pittsburgh, Pa., on Friday, May 31, 1918.

The degree of Doctor of Dental Surgery was conferred on the following graduates:

| | | | |
|----------------------|-----------------------|-------------------------|----------------------|
| Percival W. Allen | Morris W. De Hart | William P. Kennedy | Edward B. Rotheram |
| Edgar LeR. Ambrose | Samuel W. Diller, Jr. | William A. Kern | James W. Scott |
| Park R. Ashbrook | Louis I. Diss | Otto Kesel | Edward D. Shumaker |
| Elmer E. Atkinson | Edwin B. Fast | Frederick L. W. Kuhlman | John W. Sigafoos |
| John LaV. Barton | Harry E. Fettes | Isador Levy | Martin Snyderman |
| Ralph A. Bastress | Albert L. Finlay | Arthur C. Lindberg | Bert C. Sproull |
| Courtney O. Bischoff | J. Emory Franklin | Raymond C. Lutz | Howard M. Steele |
| David M. Boies | John E. Gestner | Frank M. McCarthy | Joseph I. Steele |
| John L. Boots | Lester Goldstein | William D. McClelland | Charles S. Stitt |
| Ernest M. Breed | Russell S. Halpin | Harold D. Miner | Harry H. Stoops |
| Howard F. Bristol | Fonza E. Hamilton | John W. Mitchell | James E. Stuart |
| George L. Cavanagh | Earl F. Hartley | Harold W. Moore | John B. Sutherland |
| Edwin B. Clark | Raymond A. Hayes | Foyd L. Morse | Roland M. Swank |
| Charles W. Conn | John A. Helfenbine | James V. O'Donovan | Thomas M. Taylor |
| Edwin S. Coombe | Frederick E. Henry | Francis J. Owens | Paul N. Teare |
| Harold M. Covert | George A. Hoop | Lawrence H. Peterson | Loyal B. Thomas |
| William E. Craig | Robert K. Igo | John C. Pillow | John A. Thompson |
| Alpheus J. Cross | Stewart M. Johnson | Lawrence B. Riggs | Van Burchfield Weber |
| Paul H. Deffenbaugh | Charles A. Johnston | Chester A. Robinson | Lloyd E. Weekley |
| Ernest P. De Haas | Stanley L. Kalinowski | Charles W. Rogers | Howard E. White |
| Foster L. De Hart | Robert Kaplan | Samuel H. Rosenthal | Daniel L. Young |

George Washington University Dental School.

THE ninety-seventh annual commencement exercises of George Washington University Dental School were held in Washington, D. C., on June 5, 1918.

Addresses were delivered by Joseph S. Auerbach, A.M., LL.B., and by President Stockton.

The degree of Doctor of Dental Surgery was conferred on the following graduates:

| | | | |
|---------------------------------|----------------------|--------------------------------|----------------------|
| Ralph W. S. Bonnett | Ohio | Henry C. Lowry | Michigan |
| Eugenia Butkiewicz | District of Columbia | Oscar L. Manley | Missouri |
| Elmer E. Christiansen | Utah | Hymen Popkin | New Jersey |
| John B. Copping | Maryland | Arma E. Rush | District of Columbia |
| Earl F. Danforth | District of Columbia | Gunichi Shibata | Japan |
| Hilmer A. Erickson | Minnesota | William M. Sweet | District of Columbia |
| Abraham J. Fainman | Russia | Herman H. Vordermark | South Dakota |
| George A. Flanagan | New York | Eugene LeR. Walter | District of Columbia |
| William Keroes | District of Columbia | | |

Kansas City Dental College.

THE thirty-seventh annual commencement exercises of Kansas City Dental College were held in Kansas City, Mo., on May 25, 1918.

An address was delivered by Rev. Samuel D. Harkness.

The degree of Doctor of Dental Surgery was conferred by Dr. John D. Patterson on the following graduates:

| | | | |
|----------------------|----------------------|---------------------|----------------------|
| Blythe R. Adams | Hobart S. Fulton | Clarence G. Kehl | Ralph A. Olson |
| Clarence A. Anderson | Milton P. Gardner | Herbert LeR. Kells | Marion S. Otten |
| William R. Brown | Frederick M. Garrett | Thomas P. Keyes | John E. O'Donnel |
| Floyd W. Buchanan | Arthur H. Gilfillan | Leon R. Kramer | Vernon L. Overstreet |
| Charles L. Buckner | Louis H. Gilley | Raymond O. Lane | Alan L. Pickard |
| Alonzo E. Case | Lewers D. Gray | Eugene H. Lentz | William M. Pugh |
| Walter E. Casey | Leroy Hamilton | George H. Lewis | Robert G. Reed |
| Arthur B. Chalmers | Swan C. Hamilton | William T. Longwell | Roy M. Sansom |
| John A. Corman | Maurice Hardenbrook | Albert W. Lyon | Lorenzo D. Shain |
| Claude A. Crabb | Lester B. Hill | Joseph F. McCarty | Franklin A. Smith |
| Joseph D. Crowder | Paul B. Hoffmann | Charles M. McCue | Ira T. Stewart |
| Herbert M. Culver | Ernest G. Husband | John R. McDonald | James J. Sullivan |
| Craig J. Cundiff | Rolla B. Ingram | Erle D. McEwen | Gordon L. Teall |
| Lester C. Eberhart | Frederick M. Jamar | Van Cabbage Medcalf | Dr. Masakazu Wakui |
| Frederick C. Elliott | Rexford E. Jacques | Erik Moe | Phillip T. Williams |
| William H. Euler | Joseph B. Jenkins | Lester E. Morrow | Erle Whitney |
| Irvin S. Evans | Robert D. Jordan | Charles B. Myers | Lee F. Whitson |
| Raymond L. Fox | | | |

Vanderbilt University School of Dentistry.

THE annual commencement exercises of Vanderbilt University, School of Dentistry, were held in Nashville, Tenn., on May 30, 1918.

An address to the graduates was delivered by Rev. James I. Vance, D.D.

The degree of Doctor of Dental Surgery was conferred by Chancellor James H. Kirkland, A.M., Ph.D., LL.D., on the following graduates:

| | | | |
|------------------------|-------------|-------------------------|----------------|
| Robert L. Anderson | Tennessee | Monroe L. Jarrell | Louisiana |
| James C. Austin | Illinois | Albert X. Lawrence | North Carolina |
| Ed. W. Bacon | Texas | Laurence E. Linebaugh | Florida |
| John F. Baldwin | Kansas | Hubert B. Love | Texas |
| Alfred H. Bartling | Missouri | William M. McAnally | Oklahoma |
| I. William Bull | Missouri | Raymond R. McDaniel | Alabama |
| Winston P. Caine | Mississippi | Harry T. McGlothlin | Tennessee |
| John W. Campbell | Virginia | Cecil E. Mathis | Tennessee |
| Jesse R. Carlton | Iowa | Edward J. Mahoney | Arkansas |
| Mark J. Clark | Tennessee | Malta L. Naramore | Alabama |
| Ray Cole | Georgia | Newton L. Norman | Louisiana |
| Emile M. Cuenod | Texas | William W. Petty | West Virginia |
| Cliffie A. Daniel | Tennessee | James B. Price | Mississippi |
| Carl E. Ellis | Kentucky | Rankin J. Redman | Kentucky |
| William T. Foster | Mexico | Charles F. Sowell | South Carolina |
| Christine M. Gilbreth | Tennessee | Van Albert Stilley, Jr. | Kentucky |
| Gordon K. Harmstead | Ohio | Frank L. Tapia, Jr. | Alabama |
| Hamilton D. Harper | Louisiana | Eugene H. Taylor | Tennessee |
| Thomas H. Harris, Jr. | Arkansas | Thomas L. Thomas | Florida |
| Maurice S. Howard | Tennessee | Francis C. Ulen | Indiana |
| William H. Howard, Jr. | Tennessee | John M. Vick | Tennessee |
| John B. Hurt | Tennessee | Myrtt Winton | Tennessee |
| Abner S. Ingman, Jr. | Missouri | Fred R. Woodward | Tennessee |

Texas Dental College.

THE annual commencement exercises of Texas Dental College were held in Houston, Texas, on Thursday, May 23, 1918.

The degree of Doctor of Dental Surgery was conferred on the following graduates:

| | | | |
|--------------------|-----------------------|-------------------|----------------------|
| Ernest D. Ames | Thomas Corr | Paul Knittel, Jr. | Geston M. Platt |
| Harris M. H. Ball | Wheeler W. Cunningham | Nathan B. McNutt | Jack H. Rabe |
| Andrew M. Belbeze | Lloid B. Hanson | John M. Manning | Lewis A. Roberts |
| Ditzler Brookshire | Richard G. Hardy | Walter T. Newton | Max Scholl |
| Frank J. Brophy | Shirley P. Kennedy | Frank J. Offer | Miss O. D. Sheffield |
| Milton H. Chandler | Frank L. King | Frank J. O'Rourke | Henry Tiras |

Baltimore College of Dental Surgery.

AT the annual commencement exercises of Baltimore College of Dental Surgery, held in Baltimore, Md., the degree of Doctor of Dental Surgery was conferred on the following graduates:

| | | | |
|--------------------|----------------|---------------------|----------------|
| E. L. Bailes | West Virginia | G. L. Killery | Vermont |
| H. S. Barnes | West Virginia | H. F. Killery | Vermont |
| C. C. Bell | West Virginia | W. O. Koon | West Virginia |
| L. T. Bruyette | Connecticut | L. J. Kowalski | Connecticut |
| E. M. Bullard | Massachusetts | M. Lavey | New York |
| D. A. Burt | New York | H. J. Lehr | Newfoundland |
| O. Carbonneau, Jr. | Massachusetts | J. K. Lennox | Pennsylvania |
| H. W. Causland | Maine | G. R. Lister | Canada |
| S. Z. Cervoni | Porto Rico | J. M. Loyola | Porto Rico |
| H. C. Chang | Honolulu | J. J. McCarthy | Pennsylvania |
| E. E. Chauvin | New York | J. J. McElhinney | New Jersey |
| H. G. Clements | Virginia | S. Miller | New York |
| A. J. Cobb | North Carolina | G. F. Nettleton | New Hampshire |
| M. F. Cook | Maryland | E. J. O'Day | Massachusetts |

DENTAL LEGISLATION

AND

LEGAL DECISIONS.

STATE OF NEW JERSEY.

Law Authorizing the Establishment of Free Dental Clinics in Municipalities.

THERE has recently been enacted in the State of New Jersey a Free Dental Clinic Law, which provides that hereafter municipalities may appropriate public money for the maintenance of free dental clinics for poor children of school age.

The bill was introduced by Mr. Whitney of Morris county, January 21st, was approved by the Committee on Public Health, passed both houses of the Legislature with little or no opposition, and was speedily signed by Governor Edge.

The full text of the law follows:

AN ACT

TO AUTHORIZE ANY MUNICIPALITY IN THIS STATE TO MAKE ANNUAL APPROPRIATIONS FOR THE PURPOSE OF CONDUCTING AND MAINTAINING DENTAL CLINICS IN ANY SUCH MUNICIPALITY, FOR THE FREE TREATMENT OF INDIGENT PERSONS OF SCHOOL AGE.

Be it enacted by the Senate and General Assembly of the State of New Jersey:

It shall be lawful for any board or body having control of the finances of any municipality, annually to appropriate a sum, as it may deem advisable, to be used and applied only for the maintenance and equipment, in such municipality, of a dental clinic or clinics, for the free treatment of indigent persons of school age.

—*Morris County Press.*

STATE OF NEW YORK.

Oral Hygiene Ordinance for New York City.

THE few dental clinics now operated by the department of Health exist by executive decree, and may be abolished or curtailed by the same act at any time. The purpose of this ordinance is to substitute for this makeshift organization a permanent policy and a constructive program in Oral Hygiene guaranteed by city law.

Be it ordained by the Board of Aldermen of the City of New York, as follows:

SEC. 1. There shall be established a division of Oral Hygiene in the department of Health.

SEC. 2. The purpose of such division shall be to establish and maintain such clinics and other agencies as may be necessary to secure for the children of the public schools adequate prevention and protection from dental deterioration and disease.

SEC. 3. The grades of positions within the said division shall be such as may be from time to time determined by the Board of Aldermen upon the recommendation of the Board of Estimate and Apportionment and the Commissioner of Health.

SEC. 4. The said division shall be organized immediately, and upon its organization shall take over and operate the dental clinics now existing under the jurisdiction of the said department of Health.

SEC. 5. The said division shall immediately upon its organization proceed to establish at least nine additional dental clinics in those public schools where the greatest need is found to exist, and shall from time to time continue the establishment of such further clinics as may be found necessary to carry out the provisions of this act.

SEC. 6. The Board of Estimate and Apportionment is hereby requested, pursuant to the provisions of section 188, paragraph 8, of the City Charter, to authorize the issuance of special revenue bonds in the sum of \$10,800 to provide for the permanent equipment necessary to establish such nine new clinics, and the further issuance of said bonds to an amount necessary to meet the maintenance costs of such clinics and the salaries of one dentist at the rate of \$1020 per year and one dental hygienist at the rate of \$960 per year for each such clinic from the time of the passage of this act until January 1, 1919.

[The above ordinance introduced in the Board of Aldermen of New York City should be of special interest to the profession because of the educational value which the clinics will no doubt be to the public.—ED.]

STATE OF MISSOURI.

Negligence Charged in Sterilizing Instruments—Blood Poisoning.

[ABSTRACTED FROM THE RECORDS OF THE ST. LOUIS COURT OF APPEALS.]

THAT it is a very difficult matter to connect negligence on the part of a dentist in not properly sterilizing his instruments with an infection of blood poisoning later developing in a patient's mouth, sufficiently strongly in a court of law to fix liability, is very clearly shown in the case of *Nevinger v. Haun*, recently decided in the St. Louis Court of Appeals (196 S. W. 39), wherein it is reported that—

The plaintiff, Perry Nevinger, a boy of seventeen years, had many teeth which were badly decayed. In company with his mother he went to Dr. Robinson, a St. Louis dentist, for the purpose of getting an estimate as to charges for filling certain teeth and extracting two others. The estimate not being satisfactory, they went on the following day to Dr. B. O. Haun, and the latter undertook to extract one tooth which was so badly decayed that nothing remained of it above the gum. Finding that it would be too painful to extract the tooth

using only a local anesthetic, as he at first attempted, he gave the patient the professional card of Dr. Fredericks, who made a specialty of extracting teeth and who used a general anesthetic. Nevinger did not go to Dr. Fredericks until the next day. He testified that while prior to the attempt at extraction by Dr. Haun his teeth had caused him no pain, after leaving Dr. Haun he suffered much pain during the entire night and on the following morning before going to Dr. Fredericks. After the extraction of the tooth by Dr. Fredericks, Nevinger's condition became more serious; the inflammation, swelling, and pain increased, and within a few days it was found that blood poisoning had developed.

In the suit brought by Nevinger against Dr. Haun for damages growing out of the infection there was testimony both ways as to whether the instruments used in the operation were properly sterilized before being used. There was also much testimony as to possible sources of infection in similar cases, aside from the instruments.

Dr. Fredericks testified that many kinds

of bacteria are constantly present in the mouth of the ordinary individual such as are likely to cause infection; that infections are quite common among dentists' patients; and that these are occasioned by bacteria which may be introduced in a great variety of ways, *e.g.* in food, by use of a toothpick, drinking-cup or glass, etc., or from the atmosphere alone.

Dr. Robinson testified that he found the condition of the plaintiff's mouth very bad; that the molars on each side were broken off or had decayed to the level of the gum; that "The gums were in very poor shape, not only around these teeth but around others;" that the plaintiff was complaining of pain at the time, and that "These teeth were infected before anyone touched them." He further testified that in nearly every case where a patient comes to a dentist there is some infection about the mouth, usually not serious, but that it was a very common thing for it to result in blood poisoning.

Dr. Turner, a dentist, testifying for defendant as an expert, said: "Almost everything we touch, almost every kind of utensil, has bacteria on it. Whether they develop or not in a person's mouth is a question of susceptibility and immunity. If the person is in good physical condition, probably they will not develop; but if run down, and there are a large number of bacteria in the mouth, he is likely to have a serious infection."

Dr. Flemming, another expert, who testified for the defendant, stated that it was impossible to thoroughly disinfect the mouth so that it would be surgically clean, "on account of the crevices between the teeth and cavities in the teeth, and the acid condition in most mouths."

Dr. Oatman, a physician, called as an expert, also testified that it was impossible to have the mouth surgically clean; that infection may occur though the instruments used are "absolutely sterile," and that it "happens frequently in spite of all precautions."

In passing upon this testimony, the Court said in part:

"The difficulty with plaintiff's case, as we see it, is a lack of evidence of any substantial character tending in law to show that plaintiff's injuries proximately resulted from defendant's negligence, if any, in failing, if he did, to sterilize his instruments immediately before using them. It is axiomatic in the

law of negligence that a causal connection must be established between the injury or loss suffered and the negligence with which the defendant is charged. This need not be shown by direct and positive testimony; it is sufficient if it be made to appear by inference or inferences which may be reasonably and legitimately deduced from the facts and circumstances shown in evidence. But if the evidence, when viewed in the light most favorable to plaintiff, giving him the benefit of all inferences which may be properly drawn in his favor, leaves the matter merely to speculation and conjecture, plaintiff's case must fail; for plaintiff carries the burden of adducing substantial evidence tending to affirmatively establish such causal connection.

"Under the evidence in the record before us, we think that plaintiff failed to carry the burden thus resting upon him. The infection may perhaps have originated from defendant's instruments, but, on the other hand, the opportunity for infection from a great variety of other sources was at least equally great. Testimony for the defendant makes it appear that the infection had its origin prior to the time when defendant undertook to extract plaintiff's tooth. Opposed to this is the mere testimony of plaintiff that he had not suffered pain from his teeth (though Dr. Robinson says that plaintiff came to him because of being in pain therefrom). However this may be, it is undisputed that plaintiff's teeth had been sadly neglected and that many of them were badly decayed. And the evidence shows that even where such conditions are not present the mouth contains many germs likely to cause infection, and that when the teeth are permitted to thus become decayed and rotten the danger therefrom is greatly enhanced; that infection may occur where no instruments are used, originating solely from the condition of the patient and his susceptibility to the ravages of bacteria which are ever present. And aside from this, three dentists used instruments in plaintiff's mouth in as many days.

"When the entire evidence touching the matter is received, it seems quite clear that the showing made is merely that plaintiff's injury was due to some one of several causes, for one of which only could defendant be liable; and that which of these was the *causa causans* is a matter of pure conjecture. Under such circumstances, the authorities agree that no recovery may be had."

ARMY AND NAVY DENTAL NEWS

Increase in the Naval Dental Corps.

EMBODIED in the naval appropriation bill is a provision for an increase and reorganization of the Naval Dental Corps. The draft of the bill as reported to the Senate appears below in the present issue, but several amendments were made by the Senate at the request of Senator Lodge, who explained that their purpose was to give dental surgeons the grade of dental inspector and the pay and allowances of a captain, but not the rank. It was thought desirable, he said, not to give dental surgeons the rank of captain, for the reason that in a hospital, which must be under the command of a medical officer, it might occur that a dental surgeon holding the rank of captain would outrank the officer of the medical corps in command, and thus place the dental surgeon in charge of the hospital. He said the department took the ground that they (the dental surgeons) ought not to go higher than lieutenant-commander, while members of the dental profession thought they should have the rank of captain; so the committee compromised by fixing the maximum rank to be attained at commander. In the bill as it was presented dental surgeons were given the pay and allowances of commander and captain, but without rank higher than commander. Another amendment, adopted on the floor of the Senate, provides that "All appointments or promotions provided for in this amendment shall be made by and with the advice and consent of the Senate." This amendment is a needless repetition, as the section relating to the dental corps starts with the provision "That the President of the United States is hereby authorized to appoint and commission, by and with the advice and consent of the Senate, dental officers in the navy," etc., and the addition made by the Senate is of doubtful constitutionality, as it apparently takes the appointing power away from the President. The bill provides one dental officer for each thousand of the combined *personnel* of the officers and men of the navy and marine corps, which will increase the present corps by about twenty members, and with the large increase

in the navy's complement provided in the pending appropriation bill the corps will be correspondingly enlarged. Members of the present dental corps will have the advantage of receiving credit for promotion for service rendered in an appointed status, as well as under a commission, an advantage which medical officers who served under an acting appointment did not enjoy. (The bill as proposed is printed below.)

Proposed Legislation on the Naval Dental Corps.

THE provision amending the act of June 30, 1917, relative to the Dental Corps, follows:

That the President of the United States is hereby authorized to appoint and commission, by and with the advice and consent of the Senate, dental officers in the navy at the rate of one for each thousand of the total authorized number of officers and enlisted men of the navy and marine corps, in the grades of assistant dental surgeon, passed assistant dental surgeon, dental surgeon, and dental inspector, who shall constitute the Naval Dental Corps, and shall be a part of the Medical department of the navy. Original appointments to the naval dental corps shall be made in the grade of assistant dental surgeon with the rank of lieutenant (junior grade), and all dental officers now in the dental corps appointed under the provisions of the act of Congress approved August 22, 1912 (St. at L., vol. 37, p. 345), or under the provisions of the act of Congress approved August 29, 1916 (St. at L., vol. 39, p. 573), or who may hereafter be appointed, shall take rank and precedence with officers of the naval medical corps of the same rank according to the dates of their respective commissions or original appointments; and all such dental officers shall be eligible for advancement in grade and rank in the same manner and under the same conditions as officers of the naval medical corps with or next after whom they take precedence, and shall receive the same pay and allowances as officers of corresponding rank and length

of service in the naval medical corps up to and including the rank of commander: *Provided*, That dental surgeons shall be eligible for advancement in pay and allowances, but not in rank, to and including the pay and allowances of captain, subject to such examinations as the Secretary of the Navy may prescribe, except that the number of dental inspectors with the pay and allowances of captain shall not exceed $4\frac{1}{2}$ per centum, and the number of dental inspectors with the rank, pay, and allowances of commander shall not exceed 8 per centum of the total authorized number of dental officers: *Provided further*, That dental officers shall be eligible for advancement to the pay and allowances of commander and captain when their total active service as dental officers in the navy is such that if rendered as officers of the naval medical corps it would place them in the list of medical officers with the rank, pay, and allowances of commander or captain, as the case may be: *And provided further*, That dental officers who shall have gained or lost numbers on the navy list shall be considered to have gained or lost service accordingly; and the time served by dental officers on active duty as acting assistant dental surgeons and assistant dental surgeons under provisions of law existing prior to the passage of this act shall be reckoned in computing the increased service pay and service for promotion of dental officers herein or heretofore authorized.

All appointees authorized by this act shall be citizens of the United States between twenty-one and thirty-two years of age, and shall be graduates of standard medical or dental colleges, and trained in the several branches of dentistry, and shall, before appointment, have successfully passed mental, moral, physical, and professional examinations before medical and professional examining boards appointed by the Secretary of the Navy, and have been recommended for appointment by such boards: *Provided*, That hereafter no person shall be appointed as assistant surgeon in the navy who is not a graduate of a standard medical college.

Officers of the naval dental corps shall become eligible for retirement in the same manner and under the same conditions as now prescribed by law for officers of the naval medical corps, except that section 1445 of the Revised Statutes of the United States shall not be applicable to dental officers, and they shall not be entitled to rank above commander on the retired list, or to retired pay above that of captain.

All dental officers now serving under pro-

bationary appointments shall become immediately eligible for permanent appointment under the provisions of this act, subject to the examinations prescribed by the Secretary of the Navy for original appointment as dental surgeon, and may be appointed assistant dental surgeon with the rank of lieutenant (junior grade) to rank from the date of their probationary appointments: *Provided*, That the senior dental officer now at the United States Naval Academy shall not be displaced by the provisions of this act, and he shall hereafter have the grade of dental surgeon, and the rank, pay, and allowances of lieutenant commander, and he shall not be eligible for retirement before he has reached the age of seventy years, except for physical disability incurred in the line of duty.

All acts or parts of acts inconsistent with the provisions of this act relating to the dental corps of the navy are hereby repealed: *Provided*, That nothing herein contained shall be construed to legislate out of the service any officer now in the medical department of the navy, or to reduce the rank, pay, or allowances now authorized by law for any officer of the navy.—*Army and Navy Register*.

English Army Dental Service.

CALL FOR MORE DENTAL SURGEONS.

THE Committee on Army Dental Service, under the chairmanship of Mr. D. F. Pennefather, has issued a report and made certain recommendations which we think should receive the earnest attention of those responsible for organizing the medical services for the war. The committee's recommendations, briefly stated, are: (1) That a greater number of qualified dental surgeons should be employed for the treatment of the troops. (2) That a larger number of specially skilled dental surgeons should be detailed for the treatment of jaw wounds. (3) That dental surgeons should be withdrawn from combatant and other non-combatant services and detailed for dental duties. (4) That the general organization of the dental service should be under the direction of one or more experienced dental surgeons under the orders of the Director-general of the Army Medical Service. The last is by far the most important suggestion, and we are sure that if it were acted upon the inadequacy and somewhat indifferent working of the dental service would be efficiently dealt with.

We notice that Mr. Macpherson, in a reply to Mr. Pennefather, stated that men before being sent on foreign service were examined to see if dental treatment was required, and

that such treatment, when necessary, was carried out by dental officers. In theory this may be so, but experience has shown that this examination is not always properly carried out, partly owing probably to overwork of the dental officers, and partly to a lack of proper supervision of the work of those officers. For each command in this country there is a dental adviser, but it is essential, if this office is to be efficiently filled, that men of considerable experience should be appointed and men whose judgment can be trusted.—*Lancet*.

Training Discharged Service Men as Dental Mechanics.

TECHNICAL SCHOOLS IN ENGLAND.

IN the House of Commons, Mr. Pennefather asked the Pensions Minister whether he was aware that the Liverpool Dental Hospital had established a technical school for the training of disabled sailors and soldiers in dental mechanics; and, if so, would he take steps to encourage the establishment of similar technical schools for the same purpose in other towns. Mr. Hodge replied: "A scheme for the training of discharged sailors and soldiers in dental mechanics at Liverpool Technical Institute is now under consideration. Courses of instruction have been approved and are being carried on at London, Manchester, Swansea, and Newcastle-on-Tyne, and every encouragement is being given to the establishment of courses in other towns.—*Lancet*."

American Ambulance Surgeons Awarded Legion of Honor.

As further proof of appreciation on the part of the French Government for the work accomplished at the American Ambulance in Neuilly, the Cross of Chevalier of the Legion of Honor was awarded to Mr. Louis V. Twyeffort, who was one of the founders of the hospital and a member of the committee, and later vice-chairman.

The same honor was conferred upon G. B. Hayes, D.D.S., who organized the dental department, and gave it his services from the opening of the hospital, also upon W. S. Davenport, D.D.S., who was the assistant chief of the Dental Department, and upon Dr. James P. Hutchinson, who entered upon his work for the Ambulance in June 1915, as chief surgeon of the Pennsylvania University Unit.—*New York Herald*, Paris edition.

Army Dental Corps.

THERE have been no examinations for appointment to the reserve dental corps, and there will not be for some time on account of the large number of available candidates who are on the waiting list. There are now 209 officers in the regular dental corps. In addition to this there are 5291 commissioned in the reserve corps and 257 in the National Guard, of whom about 2000 are on duty.

INSTRUCTION.

There are 160 reserve officers under instruction at Fort Oglethorpe, Ga. Every two months 80 reserve dentists are sent there for a two months' course, and every month a like number of dental assistants are sent to the same place for one month's training.—*Army and Navy Register*.

Appointments in Naval Dental Corps.

As a result of the recent examinations held at the Naval Medical School, Washington, twenty-one candidates were found qualified for appointment in the Naval Dental Corps. Commissions in the regular navy will be issued to those at the top of the list, and when all vacancies in the regular corps are filled, the remaining successful candidates will be issued temporary appointments. The dentists who passed the examinations are, in the order of their standing: E. R. Tilley, Washington, D. C.; H. A. White, Jamestown, N. Y.; E. L. Walter, Washington, D. C.; F. D. Clancy, Framingham, Mass.; E. G. Hoylman, Indianola, Nebr.; H. B. Duncan, Freehold, N. J.; J. A. Flynn, Youngstown, Ohio; E. H. Brown, Trenton, N. J.; E. H. Zimmer, Seaton, Ills.; A. L. Burleigh, Plattsburg, N. Y.; P. B. Maskrey, Martins Ferry, Ohio; A. W. Bluim, Chicago; A. H. Yando, Fitchburg, Mass.; C. H. Nelson, Jamestown, N. Y.; R. E. Dickson, West Somerville, Mass.; J. A. Kelly, Boston, Mass.; C. C. Jones, Cisco, Texas; J. E. Morgan, Washington, D. C.; R. Schmucker, Philadelphia, Pa.; J. F. Quim, New Haven, Conn., and A. Smith, New Orleans, La.—*Army and Navy Register*.

Promotions.

Dental Reserve Corps.

THE following appointments (promotions) are announced (May 18th):

To be CAPTAINS: 1st Lieuts. Fred C. Allender, Isaac H. Archer, Egbert E. Baker, Francis A. Boylan, Roscoe Bristow, Carver R. Brown, Rex P. W. Capwell, Wm. Z. Carroll, Owen L. Chesnutt, Edward E. Court-

right, George N. Frost, Robert L. Hart, Roy Hudson, Richard C. Kiebler, Paul K. McGee, Leon M. Muedeking, Edwin J. T. Simon, Wm. L. Smith, Clarence M. Van De Water, George S. F. Waldo, Clarke B. Weeks, Joseph P. Werrick, Odon J. Wilda, and Alex. J. Zimmer.

Announced May 24th:

To be FIRST LIEUTENANTS: Charles J. Denholm, Harry Holmes, Elmer H. Nicklies, Harold Jensen, Edward W. Blurock, Daniel S. Lockwood, Thomas W. Deyton, James B. Mann, Avery S. Hills, George M. Rabbitt, Judge W. Fowler, Francis S. Adams, Archie T. McGuinness, Carl H. West, Edwin M. Kennedy, Merle W. Catterlin, Thomas M. Page, Clarence P. Jackson, Chester B. Parkinson, Herbert E. Guthrie, and James H. Keith.

Announced May 25th:

To be CAPTAINS: 1st Lieuts. James E. Bailey, Wm. J. Barto, Howard Bock, Joseph L. Brown, Roy D. Gabbert, Joseph W. Golding, Henry L. Grant, Howard A. Hale, Jay M. Hisey, John O. Lessig, Clayton A. Patterson, Charles P. Shewey, Charles W. A. Spies, Ralph Burkhardt, Samuel B. Ginsberg, Guy R. Harrison, Leonard J. Heiman, Clarence B. Laffin, Cameron E. Lane, Jay H. Lee, John S. Owens, William E. Paul, Merton M. Postle, James H. Stacey, LeRoy Tileston, George E. Walker, and Raymond LeR. White.

Announced June 1st:

To be CAPTAINS: 1st Lieuts. Thomas C. F. Shirley and Robert S. Cameron.

Announced June 8th:

To be MAJOR: Capt. Max C. Frazier.

To be CAPTAINS: 1st Lieuts. Harry A. Tuckey, James T. Conner, Harry B. Riley, Leo B. Muzzy, and Howard R. Dingler.

Assignments.

Army Dental Corps.

Week ending May 18th.

Maj. Richard B. Clark to Louisville, Ky., Camp Zachary Taylor, for temporary duty in the base hospital.

Week ending May 25th.

The following to Fort Oglethorpe for course of instruction and return to their stations: Lieut.-cols. Harold O. Scott and Frank P. Stone.

1st Lieut. Robert L. Strickland from Fort Oglethorpe, Ga., to Garden City, N. Y., aeronautical general supply depot, for duty.

1st Lieut. Arthur T. Burchill from duty at Fort Oglethorpe to Charlotte, N. C., Camp Greene, for duty with 3d motor mechanics regiment.

1st Lieut. James B. Manning from Fort Oglethorpe to West Point, Miss., aviation camp, for duty.

1st Lieut. Campbell H. Glasecock from Fort Oglethorpe to duty at signal corps aviation mechanics training school, Minneapolis, Minn.

1st Lieut. James A. Curtis, Jr., from Fort Oglethorpe to Camp Greene, N. C., for temporary duty in base hospital.

1st Lieut. Neil J. McCollum from Fort Oglethorpe to Camp Greene, N. C., for duty with 4th motor mechanics regiment.

1st Lieut. William Hoblitzell from Fort Oglethorpe to Camp Devens, Mass., for duty.

The following from duty at Fort Oglethorpe to Waco, Tex., aviation mobilization camp, for duty: 1st Lieuts. Lewis W. Maly, William F. Scheumann, and William B. Stewart.

Week ending June 1st.

Col. George L. Mason from duties at Camp Dix, N. J., and will report at that camp for duty as camp dental surgeon.

Lieut.-col. Frank L. K. Laflamme from present duties at Camp Meade, Md., and will report at that camp for duty as camp dental surgeon.

Week ending June 8th.

The following from his present duties at camps specified, and report there for duty as camp dental surgeon: Col. Alden Carpenter, Camp Travis, Tex.; Col. Frank W. Wolven, Camp Lewis, Wash.; Lieut.-col. Minot E. Scott, Camp McClellan, Ala.; Maj. John L. Shock, Camp Devens, Mass.; Lieut.-col. Wm. A. Squires, Camp Sheridan, Ala.; Maj. Benjamin C. Warfield, Camp Custer, Mich.

Dental Reserve Corps.

Week ending May 25th.

Capt. Harry M. Trafford to Montgomery, Ala., Camp Sheridan, for duty in base hospital.

Capt. Max C. Frazier to Washington, for duty in army dispensary.

Week ending June 1st.

Maj. Henry W. Rich to Camp Pike, Ark., for duty.

Maj. Oscar LeR. Whitson to base hospital, Fort Riley, for duty.

Preparedness League of American Dentists.

New York City.

Preparedness League Notes and News.

By R. OTTOLENGUI, *Publicity Committee.*

COMMUNICATION FROM PRESIDENT.

THE third annual meeting of the League will take place in conjunction with the meeting of the National Dental Association on August 7, 1918.

We are preparing a program of unusual merit, and on account of the great work which has been done by the League during the past year, a general report will be given which will cover the several activities which we are engaged in.

Addresses will be made by prominent men on subjects appropriate to the occasion, and during the sessions of the convention, meetings of state directors and general workers for the League will be held for the purposes of instruction and stimulation of interest.

WHAT THE PUBLIC SHOULD KNOW.

Many drafted men apply to the dentist with the idea that the Government is paying for our services, and that they have a right to demand expensive bridge work and other attention without limit. This has come about because of the semi-military procedure of sending the notices on cards franked by the War department. Considerable embarrassment at times has been caused the dentist, and all local workers are justified in using legitimate means to acquaint the public of this misconception. It is also most essential that the public understand that all service given in the name of the League must be absolutely free. Accepting the smallest compensation aborts the spirit of the League, and cannot be justified.

Our members have been asked to give each drafted man one hour of free service, and whatever one chooses to give beyond that, the League is of course glad to receive. If it is deemed unwise to give additional service without fee, the patient should be discharged as having received that which is due him from the League, or advised to appeal to League headquarters for assignment for further attention.

LEAGUE BUTTONS.

We again urge all members to wear the League button as an indication that they are actively engaged in preparing our drafted men for service. Those not having the button may secure one by sending twenty-five cents to the treasurer, Dr. L. M. Waugh, 576 Fifth ave., New York, N. Y.

THE LEAGUE STUDY COURSE.

The League study course is designed for the mature practitioner to prepare him to give adequate service to our soldiers who have been injured in battle. Many thousands will return needing our best care, therefore it is our duty and privilege to give every assistance possible in this direction. The course will be practical in character, and approved by our best authorities. Information may be obtained by addressing the office of the president, 131 Allen st., Buffalo, N. Y.

LANTERN SLIDES.

The League has prepared 25 sets of slides, which have been distributed to the different state directors to be used by sectional units and dental societies in general. The public also may find much of interest in viewing these pictures. Each set is practically divided into two parts, one set arranged by Major Heckard, comprising nearly 90 slides, and traces the plans and development of the great work of caring for the drafted men. The evolution of the different form cards, together with their application, is graphically depicted, and is of especial benefit to directors and members of the League generally. Every district director should show these slides to his workers.

The second set of about 35 slides was arranged by J. W. Beach, and aside from conveying general information of the League and its work, gives special emphasis to the wonderful DENTAL MOTOR CAR of the League in a series of most interesting pictures. These are available through the state directors. There is a lecture in synopsis form accompanying each set of slides.

J. W. BEACH, *President.*

FROM DIRECTOR-GENERAL TO STATE DIRECTORS.

I AM inclosing herewith copy of the report prepared by Major Heckard up to May 1, 1918.* This will give each state director an opportunity to see just what has been done in his state up to May 1st.

The grand total for the United States is

* See Statistical Report, preceding page.

236,115 operations. This is a fine showing, but we are going to make it 1,000,000 operations.

Don't criticize the states that have a small number of operations reported. Their required quota may not have been as big as yours, and then, too, some states have only recently got started. Just watch the reports from now on and see them grow.

In a few days we will send you a report of the work done to June 1st, and thereafter each month. There's a big surprise coming in that June report.

The dental profession is going on record. Our part in winning the war is to make our boys dentally fit. Let's push that 1,000,000 operations "over the top." See if you cannot do two things: First, secure 100 per cent. of the dentists in your state as members of the League; and second, secure the co-operation of members to send in reports. Application blanks in any desired quantity will be forwarded to you upon request.

The inclosed report is nothing like as large as it would have been if a form 3-c card had been returned to our headquarters at 50 E. 42d st., New York City, for every operation. Unfortunately, many men do not see the necessity of making these reports, and I feel sure that at least 150,000 operations have been performed of which we have no record. If, therefore, you want your state to make as good a showing as possible, it is essential that you impress upon all members of the League in your state through your county directors the necessity for returning a form 3-c card to our headquarters for every operation performed.

With the German U-boats at our very doors let our profession give its answer—More sacrifice for ourselves—More help for our boys.

Major Heckard, who has been so untiring in his devotion to the work of the League, will leave our headquarters on June 11th, and proceed to Camp Greenleaf, Fort Oglethorpe, to prepare himself for special services in another field of activity in the Dental Reserve Corps. His loss to the League will be greatly felt by everyone, particularly at headquarters, and I am sure the best wishes of all our directors will follow him in his new field of action. We need your co-operation more than ever, and bespeak for his success, or when appointed the same hearty co-operation which has been accorded Major Heckard.

Yours very truly,
CHAS. F. ASH, *Director-general.*

FROM MAJOR HECKARD

I AM in receipt of your communication of June 7th congratulating me on the change I am making, and asking that I write "a short good-bye letter to the boys of the League for publication in the magazines." I will make it read "members" because there are a good many women dentists giving free dental service.

At this time I can simply state that my request to be relieved of the supervision of the Preparedness League of American Dentists and assigned to further military duty having been granted, and before I report to the officers' training camp, Camp Greenleaf, Chickamauga Park, Ga., I would like to thank the officers and members of the Preparedness League of American Dentists and all other persons who helped to make free dental service possible for the men of our new National Army.

I do not consider this work much more than started, although we have reported at this office nearly 400,000 operations to date. I feel confident that with the same co-operation and support which has been given me continued, the League will very soon be able to report 1,000,000 free dental operations.

I hope the day is not far distant when every American dentist will be a member of the Preparedness League of American Dentists.

W. M. HECKARD.

FROM CHAIRMAN OF MOTOR CAR COMMITTEE.

In order to get the dental motor car project properly before the dental profession and give them an idea of what has already been done in the way of the first models, I am asking the editors of all the magazines to publish the following statement:

It has been arranged by the chairman of the Dental Motor Car Committee to have sent to any person interested in Dental Motor Cars sets of photographs showing all details of the car direct from the photographer at the following prices:

| | |
|-------------------------------|--------|
| 1 set 10 plain prints | \$2.00 |
| 1 set 10 linden prints | 2.50 |
| 1 set 10 lantern slides | 5.00 |

Send to the following address for these photographs: Harry C. Beitt, 12970 Emerson ave., Cleveland, Ohio, commercial photographer.

S. M. WEANER,
Chairman Motor Car Committee.

SPECIAL NOTICE.

To the Graduates of the PENNSYLVANIA COLLEGE OF DENTAL SURGERY.

ACTION OF THE BOARD OF CORPORATORS.

WHEN the Pennsylvania College of Dental Surgery closed its doors as a teaching institution there remained in the hands of the Board of Corporators a sum of money to be disposed of by the board. Several suggestions were made as to what might be the most desirable purpose for which this fund could be used. One was to establish free beds in a hospital for the benefit of dentists; this suggestion was found to be not in accordance with law. It was then suggested that the fund be given to the Research Foundation of the National Dental Association or to the Thomas W. Evans Museum and Dental Institute of the University of Pennsylvania.

The Court appointed Horace L. Henderson, Esq., of Philadelphia, a Master empowered to take testimony and make recommendations as to the final disposition of the fund.

Several hearings took place, and after listening to much testimony the Master

recommended to the Court that the fund be awarded to the Trustees of the University of Pennsylvania in trust for the establishment of a research foundation to be designated by the name of The Pennsylvania College of Dental Surgery, the income thereof to be used in the School of Dentistry of the University of Pennsylvania, now affiliated with the Thomas W. Evans Museum and Dental Institute, for scientific research and investigation in dentistry, and in the purchase of books related or necessary thereto.

The foregoing recommendation was duly confirmed by decree of the Court, February 18, 1918.

The award also includes the archives of the Pennsylvania College of Dental Surgery upon its dissolution, which are turned over to the Trustees of the University of Pennsylvania for safe-keeping and any necessary beneficial use.

ROBERT HUEY, D.D.S., *President*,
J. HOWARD GASKILL, D.D.S., *Sec'y*,
Committee Alumni P. C. D. S.

SOCIETY NOTES AND ANNOUNCEMENTS

NOTICES should reach the Office of the DENTAL COSMOS *not later* than the 11th or 12th of the month preceding that of publication.

Coming Dental Society Meetings.

National.

NATIONAL DENTAL ASSOCIATION. Chicago. August 5th to 9th.

NATIONAL ASSOCIATION OF DENTAL FACULTIES. Chicago. August 2d and 3d.

NATIONAL ASSOCIATION OF DENTAL EXAMINERS. Chicago. August 5th and 6th.

AMERICAN ACADEMY OF ORAL PROPHYLAXIS AND PERIODONTOLOGY. Chicago. August 2d and 3d.

AMERICAN SOCIETY OF ORTHODONTISTS. Chicago. August 1st to 3d.

ASSOCIATION OF MILITARY DENTAL SURGEONS. Chicago.

CANADIAN DENTAL ASSOCIATION. Chicago. August 5th to 9th.

DELTA SIGMA DELTA FRATERNITY. Chicago. August 5th.

PSI OMEGA FRATERNITY—NATIONAL ALUMNI CHAPTER. Chicago. August 5th.

XI PSI PHI FRATERNITY. Chicago.

State Meetings.

JULY.

CALIFORNIA STATE DENTAL ASSOCIATION. San Francisco. July 8th to 13th.

INTERSTATE DENTAL ASSOCIATION. (Col'd.) Buckroe Beach, Va. July 10th to 12th.

MONTANA STATE DENTAL SOCIETY. Butte. July 18th to 20th.

NEW JERSEY STATE DENTAL SOCIETY. Atlantic City. July 17th to 19th.

Examiners' Meetings.

MAINE BOARD OF EXAMINERS. Augusta. July 1st.

MONTANA BOARD OF EXAMINERS. Helena. July 8th to 11th.

NORTH DAKOTA BOARD OF EXAMINERS. Fargo. July 9th.

SOUTH DAKOTA BOARD OF EXAMINERS. Sioux Falls. July 1st.

New Jersey State Dental Society.

THE forty-eighth annual convention of the New Jersey State Dental Society will be held on July 17, 18, and 19, 1918, on Young's Million Dollar Pier, Atlantic City, N. J.

The entire convention will be held on the pier. Machinery Hall will be used for the exhibits. Those who attended last year will remember the magnificent display of dental goods, and Dr. S. I. Callahan of Woodstown, N. J., chairman of the Exhibit Committee, with 25,000 square feet of space, has promised an exhibit greater than that of 1917.

The Essay Committee, under the direction of Dr. C. M. F. Egel of Westfield, will present two or three essayists of prominence—names and subjects to be announced.

Machinery Hall extension, with 10,000 square feet of space, will give ample room for clinics. Dr. Edward Stillwell of Glen Ridge, N. J., is chairman of the Clinic Committee, and has already arranged for many new and interesting clinics. This section will be of special interest.

All meetings for the presentation of papers as well as the business meetings will be held in the Greek Temple, out on the pier.

The headquarters of the society will be at the pier entrance. Mail may be directed to exhibitors, clinicians, or members in care of the Secretary New Jersey State Dental Society, Young's Million Dollar Pier.

A cordial invitation is extended to ethical practitioners.

JOHN C. FORSYTH, *Sec'y.*
430 E. State st., Trenton, N. J.

National Dental Association.

TWENTY-SECOND ANNUAL MEETING,
Chicago, August 5th to 9th.

SPECIAL ANNOUNCEMENT OF HOTELS AND GARAGES.

THE National Dental Association will hold its Twenty-second Annual Meeting in Chicago, August 5-9, 1918. The headquarters will be at the Auditorium and Congress Hotels, situated on Michigan ave., cor. Congress st. All meetings, clinics, and exhibits will be held in these two hotels, which are connected by an underground tunnel.

The important announcement at this time must be the warning: RESERVE YOUR ROOMS AT ONCE. Make reservations by mail direct to the hotel of your choice. Arrangements for parking cars should be made direct to the garage.

Hotels.

Following are the rates of the two hotels:

Auditorium Hotel (Michigan Boulevard and Congress st.): Single room without bath, \$1.50 and \$2.00 per day. Single room with bath, \$2.50 to \$4.00 per day. Double room without bath, \$2.50 and \$3.00 per day. Double room with bath, \$4.00, \$5.00, and \$6.00 per day.

Congress Hotel and Annex (Michigan ave. and Congress st.): Room, detached bath (one person), \$2.00, \$2.50, \$3.00 per day. Room, private bath (one person), \$3.00, \$3.50, \$4.00, \$5.00, \$6.00 per day. Room, detached bath (two persons), \$3.00, \$4.00, \$5.00 per day. Room, private bath (two persons), \$5.00, \$6.00, \$7.00 per day. Suites: Two connecting rooms, private bath (two persons), \$6.00 to \$10.00 per day. Three or four persons, \$8.00 to \$14.00 per day.

Corner suites: Parlor bedroom and private bath, \$10.00 to \$50.00 per day.

Garages.

The following is a list of garages and rates:

CITY AUTO PARKING COMPANY.

(A. V. Jackson, Gen. Mgr.,

Michigan ave. and Lake st., Chicago, Ill.)

Our rates for storage are \$1.00 for the first 24 hours, and 75 cents each additional 24 hours. At these rates cars can be taken out for driving and reparked during the same 24-hour period at same charge.

DOWN TOWN GARAGE.

(A. J. Bemmer, Mgr.,

Michigan blvd. and Eighth st.)

"We are prepared to take care of thirty or forty cars during your convention, at a special rate of 75 cents per day, providing they notify us of their identity as members of your association."

One thousand cars can be parked in Grant Park (on the Lake Front) free. The city of Chicago furnishes policemen to watch these cars.

J. P. BUCKLEY,

Chairman Publicity Committee.

GENERAL CLINIC.

Arrangements are sufficiently advanced to promise the members of the Association that the general clinic will be one of the great features of the 1918 meeting.

In conference with officers of the National Dental Association, the committee in charge of the general Clinic carefully considered the nature of the clinic to be presented this year. After trying for the past few years new features in conducting the clinic program, it is the belief that a greater number will be served and benefited by holding a General Clinic, grouped in sections: Operative, Prosthetic, Crown and Bridge Work, Orthodontia, and Prophylaxis.

To make it National in character, the presidents of the different state societies were requested each to appoint two clinicians and two associates from his state society.

Up to date, thirty-nine state societies are represented, and the remaining nine will be represented before the publishing of the official program.

Far-away Alaska is sending two, and two associates, and to make the Clinic more than National—in fact, an "Allied" affair—the Canadian Dental Association has promised ten of the best clinicians in the Dominion. In addition, there will be a few unit clinicians who will demonstrate principles that require more than two men.

It is safe to say that this Clinic will be unique in the sense that every man on the program will either be present or be represented by his associate.

DON M. GALLIE,

Chairman General Clinic.

NOTE.—The Program of the Chicago Meeting had not come to hand at the time of closing the DENTAL COSMOS forms for the July issue.—Ed.

[AT CHICAGO.]

Canadian Dental Association.

THE Canadian Dental Association has accepted the very kind invitation of the National Dental Association to meet with them in Chicago, August 5 to 9, 1918.

SYDNEY W. BRADLEY, *Sec'y.*

[AT CHICAGO.]

National Association of Dental Examiners.

THE next meeting of the National Association of Dental Examiners will be held in Chicago, Ill., August 5 and 6, 1918, at the Auditorium Hotel.

For further information address

J. A. WEST, *Sec'y*,
417 Utica Bldg., Des Moines, Iowa.

[AT CHICAGO.]

National Association of Dental Faculties.

THE next annual meeting of the National Association of Dental Faculties will be held in the Green Room of the Congress Hotel, Chicago, Ill., August 2, 1918, at noon. The Executive Committee will meet at 10 A.M. on the 2d. The meeting will continue through August 3d.

CHAS. C. ALLEN, *Sec'y*,
N. W. cor. 10th and Troost, Kansas City, Mo.

American Academy of Oral Prophylaxis and Periodontology.

THE fifth annual meeting of the American Academy of Oral Prophylaxis and Periodontology will be held August 2 and 3, 1918, at Edgewater Beach Hotel, Chicago, Ill.

GRACE ROGERS SPALDING, *Sec'y.*

[AT CHICAGO.]

American Society of Orthodontists.

THE eighteenth annual meeting of the American Society of Orthodontists will be held August 1, 2, and 3, 1918, at the Edgewater Beach Hotel, Chicago, Ill.

This will be an excellent meeting. It is advisable to make your reservations early.

F. M. CASTO, *Sec'y*,
Rose Bldg., Cleveland, Ohio.

[AT CHICAGO.]

Delta Sigma Delta Fraternity.

THE thirty-fourth annual meeting of the Supreme Chapter of Delta Sigma Delta Fraternity will be held in the Florentine Room of the Congress Hotel, Chicago, on Monday, August 5, 1918, at 9 A.M.

Headquarters of the Fraternity will be at the same hotel, where the annual banquet will also be held in the evening, in the Gold Room. (Notify Dinner Committee *at once.*)

By order of the Supreme Chapter.

HY. W. MORGAN, *Supreme Gr. Master.*

R. HAMILL D. SWING, *Supreme Scribe.*

[AT CHICAGO.]

Psi Omega Fraternity.

THE National Alumni Chapter of the Psi Omega Fraternity has established headquarters during the National Dental Association meeting at Room 230, Auditorium Hotel.

The business session of the National Alumni Chapter will be held in the New Ballroom of the Auditorium Hotel, Monday, August 5th, at 2.00 P.M.

The Psi Omega banquet will be held in the Florentine Room of the Congress Hotel at 7.00 P.M., Monday, August 5th.

Psi Omegas who expect to attend the banquet should communicate at once with Dr. M. M. PRINTZ, 4235 Lake Park ave., Chicago.

Montana State Dental Society.

THE fifteenth annual session of the Montana State Dental Society will be held at Butte, Mont., July 18, 19, and 20, 1918.

R. R. JOHNSON, *Sec'y*,
Great Falls, Mont.

California State Dental Association.

THE California State Dental Association will hold its regular annual session for the year 1918 in San Francisco, July 8 to 13, 1918.

We will conduct our meeting this year on the Oklahoma plan, and feel that we can assure all who attend a pleasant as well as a profitable meeting. Further information may be obtained by addressing

JOHN E. GURLEY, *Sec'y*,
350 Post st., San Francisco.

Montana Board of Examiners.

THE Montana State Board of Dental Examiners will hold a session for examination July 8, 9, 10, and 11, 1918, at Helena, Mont. Applications should be in the hands of the secretary fifteen days before the meeting.

G. A. CHEVIGNY, *Sec'y*,

107 Yegen Bank Bldg., Butte, Mont.

South Dakota Board of Examiners.

THE next meeting of the South Dakota State Board of Dental Examiners will be held at Sioux Falls, S. D., beginning promptly at 9 o'clock, Monday morning, July 1, 1918.

All applications must be in the hands of the secretary by June 24th. Fee for examination \$25. No reciprocity or interchange. Full information and application blanks may be received by addressing

L. S. SPENCER, *Sec'y*,

Watertown, S. D.

North Dakota Board of Examiners.

THE next meeting of the North Dakota State Board of Dental Examiners will be held at Fargo, July 9, 1918. All applications and credentials must be in the hands of the secretary July 1st. For application blanks or further information address

W. E. HOCKING, *Sec'y*,

Devils Lake, N. D.

Maine Board of Examiners.

THE Maine Board of Dental Examiners will hold their regular examination, beginning July 1, 1918, at 8.30 A.M., at the State-house.

All applications and fee, \$20, must be in the hands of the secretary by June 21, 1918.

The examination for DENTAL HYGIENISTS will be given at the same time; fee \$10.

WILL S. PAYSON, *Sec'y*,

Castine, Maine.

National Mouth Hygiene Association.

DEPARTMENT OF EXTENSION LECTURES.

A COMPLETE lecture set, consisting of full manuscript and thirty-six specially selected and prepared lantern slides covering the subject of Mouth Hygiene, is furnished by this association to members of state dental societies and others who may be considered as qualified to present the subject on the lecture platform.

For rental and sale terms and other particulars address the undersigned.

EDWIN N. KENT,

Director of Extension Lectures,

330 Dartmouth st., Boston, Mass.

Forsyth Dental Infirmary for Children.

NEW DEPARTMENT—LIBRARY AND MUSEUM.

THE trustees and director of the Forsyth Dental Infirmary for Children have authorized the creation of a new department, to be known as the "Library and Museum." They solicit from the dental profession contributions of books and dental periodicals, particularly those out of print and not readily obtainable by purchase; also specimens of dental abnormalities, cast, or specimens of unusual structures of dental interest, for all of which permanent acknowledgment will be given.

FREDERICK A. KEYES, D.M.D.,
Librarian and Curator of Museum.

ORIGINAL COMMUNICATIONS

The Pathogenesis and Prophylaxis of Pyorrhea Alveolaris.

By Dr. MAURICE ROY, Paris, France,

PROFESSOR IN THE DENTAL SCHOOL OF PARIS; DENTIST TO THE HOSPITALS OF PARIS.

(Report presented to Section III, Dental Surgery and Therapeutics, of the Sixth International Dental Congress, London, 1914.)

(I.)

Introduction.

THE pathogenesis of pyorrhea alveolaris is one of the most controverted points of dental pathology, both in regard to its general conception and from the point of view of the initial lesion of the disease.

The differences existing between various authors appear to me to be attributable to two reasons:

First, because often under the name of pyorrhea alveolaris are included several different diseases, which, although they have points in common, are nevertheless clearly distinct, if attention is paid to their essential characteristics.

Second, because the majority of authors, examining the disease in its advanced stages, involuntarily confuse secondary with primary lesions, and

consequently the adjuvant causes with essential causes; for at this stage these causes can no longer, except with great difficulty, be distinguished from each other.

It is of the greatest importance to determine the initial lesion of pyorrhea, because it is upon this knowledge that the character of the early treatment depends. It appears to me desirable to study this question from a standpoint which hitherto has not been sufficiently considered. For this purpose, having first definitely determined what is understood by the term pyorrhea alveolaris, I have taken successively all the lesions observed in the course of the disease and sought to establish the rôle which each of these plays in the evolution of the disease.

In order to avoid all sources of error, I have studied the disease more particularly at the period of its beginning, very much earlier than have a number of observers, and have endeavored to separate it from other affections with which it is very frequently associated in its course, and which may almost completely mask the initial lesion of the disease. I have, further, shown the logical evolution of pyorrhea and the rôle played therein by incidental causes; and finally, I have devoted the last portion of this work to the early prophylaxis of this disease, which is intimately connected with a knowledge of these first postulates. I have endeavored to discuss as impartially as possible the diverse opinions expressed upon the subject of pyorrhea, while studying especially the more recent works on this subject.

The bibliography of pyorrhea is extensive. Some idea of its extent may be gained when I say that the International Institute of Bibliography at Brussels has furnished me with more than 500 bibliographical references on this subject. The excellent study of Julien Tellier upon pyorrhea constitutes one of the best on this subject, and has been very useful to me in the preparation of this paper. I have been able to cite only a few other authors, in order not to prolong too greatly my study.

Part I.

CHAPTER I.

CHARACTERISTIC SYMPTOMS OF "PYORRHEA ALVEOLARIS."

What do we understand by the term pyorrhea alveolaris? I do not fail to realize that the term is faulty, since it relates to a symptom which may even be lacking in pyorrhea, and one which, at all events, is not characteristic of this disease; but I employ it here because of having to take into account the universality of its usage. Likewise, I shall study more particularly the most generally observed form of pyorrhea; and, in order not to be misunderstood, I shall outline the clinical picture of the disease at its mature period, so as to spe-

cify from the beginning that symptomatic complex which we have agreed to designate by the term "pyorrhea alveolaris."

At the mature period, then, pyorrhea alveolaris presents a series of clearly determined symptoms, namely:

(1) Looseness and irregularity of the teeth.

(2) Gingival inflammation over a greater or lesser area.

(3) The existence at the neck of the tooth of a more or less deep pocket along the root.

(4) Denudation of the root, which no longer has a pericemental ligament, and of all that portion covered by the pocket.

(5) The habitual presence of calculus upon the root in that portion which is deprived of pericementum.

(6) More or less abundant suppuration in the gingival pocket.

In this symptomatic ensemble, one single phenomenon stands out as clearly characteristic. This is the gingival pocket. This is why I think one should accept as a principle that what characterizes pyorrhea alveolaris at its mature state is the presence of a more or less deep pocket at the neck of the tooth, with corresponding denudation of the root in that portion covered by the pocket. All the other observed phenomena are in relation with this lesion, either as cause or effect. It is, then, the pathogenesis, the mode of formation, of this pocket which is likely to give us the exact pathogenesis of the disease.

CHAPTER II.

CAUSES OF LOCAL ORIGIN.

All the symptoms which accompany pyorrhea have been invoked as the cause of the affection, and consequently of the formation of the pocket. Accordingly, we must review each of these symptoms, in order to see if one of them can be considered as the initial lesion which would entail the formation of the characteristic pocket of the disease.

(1) *Gingivitis*. Chronic gingivitis can present a symptomatic ensemble

which approximates so markedly pyorrhea alveolaris in its developed condition that a number of authors, as Riggs, Miller, Landgraf, and many others, would interpret pyorrhea alveolaris as a simple chronic gingivitis.

But it would be erroneous to decide on their identity from the great points of resemblance between these two diseases; for if the number of people affected with pyorrhea alveolaris is large, that of people affected with chronic gingivitis from complete lack of any dental hygiene is still larger. It would then be necessary to explain why, with identical conditions, and often even much more unfavorable from the point of view of gingival inflammation and infection, some individuals often remain free from true pyorrhea during an indefinite period.

On the other hand, the existence of a gingival pocket with corresponding denudation of the root being the characteristic lesion of pyorrhea alveolaris, it would be necessary to explain why, among people presenting intense chronic gingivitis of a number of years' duration, one finds at the necks of the teeth only slightly modified gingival pockets, while among pyorrrhetics with a very slight marginal gingivitis one observes noticeable gingival pockets, often going even to the apices of the roots.

In order to explain this difference it is necessary to have other etiological factors intervene, whose presence is indispensable in pyorrhea—which fact permits the gingivitis to be considered only as an incidental cause.

Again, if pyorrhea is frequently accompanied by gingival inflammation, yet this latter symptom may be totally absent in various phases of the disease, and may also be absent at the beginning, as I shall show. This consideration alone suffices to eliminate gingivitis as an initial lesion of pyorrhea alveolaris, which is distinguished very clearly by its development, its course, and its outcome from gingivitis, which latter comes only as a complication of pyorrhea—by a mechanism which I shall explain later.

(2) *Salivary and so-called serumal calculus.* The presence of calculous deposits upon the necks of the teeth and upon the denuded parts of the roots is a phenomenon almost constant at the mature stage of the disease. The majority of authors divide these deposits into two classes—one of a salivary, the other of a sanguineous origin, according as the deposit is located on the uncovered portion of the tooth (salivary calculus) or upon that part of the tooth covered by soft tissue (serumal calculus). This is a division which may be somewhat arbitrary, and perhaps the difference does not lie in the origin, but merely in different conditions of formation.* However that may be, these different deposits always accompanying gingivitis are considered by a number of authors as the factor which is productive of the pyorrrhetic pocket. Indeed, tartar, by its successive depositions at the neck of the tooth, and the inflammation it produces in the gum, determines a progressive recession of this tissue; as the tartar is deposited at a level farther from the neck the root is progressively denuded and despoiled of its pericementum and of its alveolar walls, which are resorbed as the result of the extension of the intense gingival inflammation. The extension of these disorders may lead finally to the loss of the tooth by extension of the tartar into the apical region.

While this process is noticeably similar to that met with in pyorrhea, it differs, nevertheless, from this latter disease in essential points. The pocket formed solely by tartar deposits is always proportional to their abundance; they almost completely fill the pocket, the gum being resorbed *pari passu* with the deposition of the tartar. In pyorrhea, on the contrary, even in the absence of any apparent deposit of tartar, with the gum still appearing to embrace the neck of the tooth, a very deep pocket may be observed, extending even to the apex, and completely independent of the abun-

* We shall speak later of the so-called uratic deposits.

dance of calcarious deposits. The so-called serumal calculi always occupy but a very small portion of the pocket.

H. Burchard,* finally, has shown that—

If the tooth be extracted at a comparatively early date, a dark, scaly calculus is seen to occupy the cervical portion of the root; beyond this is an area of tooth denudation, in which no deposits are found, and, toward the apex, the shreds of the thickened pericementum. There is always a space between the pericementum and calculus, showing that detachment or loss of the pericementum is in advance of the calculus.

Again, in pyorrhea the suppuration which exudes from the pyorrhetic pockets is sufficiently abundant to have given its name to the disease, and is quite often the first sign which attracts the attention of patient and dentist to some teeth that are free from calcarious deposits upon their coronal portions. In the periradicular resorption produced by simple calculous deposits, on the contrary, the suppuration is relatively insignificant, even with considerable calculous deposits, because of the slight depth of the gingival pockets.

From these various considerations it is evident that neither the gingivitis, nor the salivary, nor the so-called serumal calculi can be considered as constituting the initial lesion of pyorrhea alveolaris. Without doubt, as I shall show, they play a very important rôle in the development of the disease, once this is established by the initial lesion, but nevertheless they constitute only adjuvant causes of pyorrhea.

(3) *Infection.* If the suppuration which has given its name to pyorrhea can be absent in certain cases, even at the period of maturity of the disease, and if it be totally wanting at the beginning, yet infection, which it indicates, is none the less the habitual accompaniment of pyorrhea. Certain authors, following Galippe, have attempted to incriminate this infection as the primary cause of the disease. They have even gone to the

point of claiming that it is a contagious disease, passing from tooth to tooth and from individual to individual.

To admit this hypothesis, it is not sufficient to find in the gingival pockets a more or less considerable number of micro-organisms, for it is possible to find them in all parts of the most healthy mouths—for, as we know, these have an abundant microbian flora. It would be necessary, before accepting the infection theory, to establish the constant presence in pyorrhetic pockets, or in the periradicular tissues, of a specific microbe; but the researches of all observers, without exception, show that the bacteria found in pyorrhetic pus present absolutely nothing specific, and are either streptococci or staphylococci, which are met in ordinary suppurations, associated with saprophytes, ordinary inhabitants of any healthy mouth.

It is, furthermore, contrary to all observation that pyorrhea is contagious from tooth to tooth, for this affection begins most often in isolated teeth, frequently avoiding adjacent teeth—that is to say, those which are exposed to the most direct conditions of contagion. It would be still more puerile to discuss contagion from individual to individual, for in so widespread a disease such an assumption rests upon no foundation.

Finally, if the theory of a previous infectious cause were accepted, it would still be necessary, as far as gingivitis is concerned, to explain why many individuals with badly infected mouths do not have pyorrhea, while this disease is met with in mouths which have always been well cared for. To explain this contradiction, the partisans of the infection theory have been obliged to admit that it is an infection developing only among those having an individual predisposition.* In these conditions, the infection is only a secondary element of the disease, coming into play only when it is already established. This could not be

* H. Burchard: "Varieties of Dental Calculi," DENTAL COSMOS, 1898, p. 1.

* Galippe, in a communication to the International Medical Congress, Berlin, 1890; H. Ferré, "De certaines Infections secondaires d'origine buccale," Thèse de Paris, 1906.

the initial lesion of pyorrhea, nor the primary cause of the formation of the gingival pockets characteristic of the affection.

(4) *Traumatic causes.* In the opinion of a number of authors, the primary lesions in pyorrhea would be troubles of traumatic origin, due either to malocclusion (Karolyi, Vienna) or to malpositions—in a word, to what Godon has called “ruptures of the equilibrium of the dental system,” or, finally, to local irritations, as those resulting from fillings defective at the cervical margin, the absence of the point of contact between the teeth, and the piling up of food between teeth so placed, etc.

All these causes incontestably intervene in the evolution of pyorrhea, where they play the rôle of predisposing causes. But to be really the primary cause of this affection they would have to be encountered in all cases of pyorrhea without exception, and would have to precede the evolution of the disease; for a single case of pyorrhea without a similar pre-existing cause suffices to destroy the whole theory. But it is incontestable that pyorrhea is seen to develop in persons free from any malocclusion, or malposition, or traumatic irritation. On the other hand, a number of individuals present malocclusion associated with malpositions and buccal infection from the lack of hygiene, who remain unattacked by pyorrhea, although there are present in their mouths many conditions considered capable of provoking this affection. It is therefore necessary, for this disease to occur, that another factor intervene, which factor alone can be considered as the initial lesion.

The irritations caused by defective fillings or poorly fitted bands or crowns can no longer be discussed, because, unfortunately, the number of defective fillings is considerable, and there are throughout the world thousands of individuals carrying similar fillings and crowns without as a consequence having pyorrhea. In addition to this, the opinion is unanimous that dental caries is rare among those affected with pyorrhea, and consequently few fillings, as a rule,

are met with in their mouths. It may even frequently happen, as I have had occasion to observe, that teeth having defective fillings are the last affected among pyorrhethics.

The absence of point of contact is open to the same criticisms as dental malocclusion and malpositions; and as to the piling up of food in abnormal interdental spaces, we shall see that this phenomenon is not primary, but, on the contrary, is quite often secondary to the initial lesion of pyorrhea.

To summarize: All the traumatic causes may be present without pyorrhea; on the other hand, pyorrhea may develop without these traumatisms. Consequently the injuries inflicted upon the teeth by these several factors cannot be considered as primary features of the disease.

CHAPTER III.

CAUSES OF GENERAL SYSTEMIC ORIGIN.

Having thus eliminated successively, as the initial lesion of the disease, gingivitis, salivary and serumal calculi, infection, and traumatic injuries (that is, the ensemble of causes which would tend to make of pyorrhea a purely local disease), we now arrive at a different order of causes, which present this feature in particular: That whatever be the tissue wherein the primary lesion of the disease occurs, general systemic causes must intervene in its development—that is, the development of the disease is related to a particular weakness in the constitution of the individual.

I do not hesitate a moment to affirm that, in spite of the important rôle played in its development by local causes, pyorrhea alveolaris is a disease having origin in general causes, and that without this conception it is impossible to explain the development of this disease, which does not attack certain individuals in whom all the local causes are present, while, on the other hand, it attacks certain other individuals in whom these causes are totally lacking.

Following the very judicious expression of Julien Tellier, it is impossible to admit a centripetal progression of pyorrhea

alveolaris, as is insisted upon by the partisans of the external causes which have just been enumerated. This affection progresses centrifugally, and it is a general cause which determines the production of the initial lesion which will permit of the later development of the disease.

These general causes are probably numerous, and I do not propose to enumerate them here in detail, referring for that to the excellent study by Julien Tellier. Suffice it is to say that, with almost unanimous accord, the several authors have confirmed the views first expressed by Magitot, namely, that it is arthritism and its associated affections which are the diseases most often incriminated as giving origin to pyorrhea.

But whatever be these general causes, they are the ones which, exercising their action upon dental or alveolar tissues, determine there the initial lesion which will give birth to the symptomatic complex which it has been agreed to designate by the term pyorrhea alveolaris.

What is the tissue primarily modified by this particular general condition? That is what we are now about to try to establish by studying the different lesions observed and the theories expressed by different authors.

(1) *The tooth pulp.* The teeth attacked by pyorrhea undoubtedly present a particular structure which exhibits a remarkable immunity to dental caries. All observers are practically in accord upon the point that dental caries is, if not exceptional, at all events, quite rare, among pyorrhetic patients. This circumstance even constitutes for them a constant source of astonishment, when they observe the loss of teeth which seem to them affected by no apparent alteration. It is, indeed, remarkable that in a pyorrhetic patient who may have carious teeth, these are often the very teeth which are last attacked by the disease. This fact impelled Paul Dubois to enunciate the principle that "Expulsive periodontitis is in inverse ratio to caries." With this fact as his foundation this author has established a theory of pyorrhea which refers it to an early senility of

the tooth resulting from its excessive calcification.* This alteration of the tooth would be an early over-calcification analogous to that which physiologically occurs among the aged.

This excessive mineralization of the tooth is in relation with pulpal over-activity; and indeed, dentinal calculi are frequently found in teeth affected by pyorrhea. This theory also has some phases in common with that which would place the primary lesion in the pulp. Josipowici would lead us to believe that all teeth affected with pyorrhea present pulpitis with inflammatory reaction in the periodontal ligament.

These theories find support in a fact of current observation that teeth with devitalized pulps are less frequently attacked by pyorrhea than others. On this observation is based the treatment which consists in devitalizing pyorrhetic teeth.†

Just here we wish to express an opinion which, we believe, has not yet been expressed in this connection, viz, that this observation applies especially to those teeth whose pulps were dead *before the invasion of pyorrhea*. Those teeth whose pulps had been destroyed at a relatively early age enjoy a consider-

* The vitality of the alveolo-dental ligament is dependent upon the more or less compact texture of the tooth, upon the diameter of the dentinal fibrillæ, and upon the proportion of organic matter which the tooth contains. Teeth rich in organic matter and poor in mineral salts are the teeth which are very susceptible to caries, i.e. young teeth. Teeth rich in mineral content and poor in organic matter are slightly susceptible to caries. Their attachments are not strong; their loosening and early loss result from this over-mineralization; the pulp dies of calcification, which takes place at its periphery, and the alveolo-dental ligament undergoes the same retrogressive evolution. (Paul Dubois, "Périodontite expulsive, ou Ostéo-périostite alvéolo-dentaire," *l'Odontologie*, 1892, p. 7.)

† Because of the anastomosing relations which exist between the pulpal circulation and the alveolar and pericemental circulation, the destruction of the pulp brings about, perhaps, circulatory over-activity in the periradicular tissues, which would prevent the development of pyorrhea.

able degree of immunity toward pyorrhea, while this immunity is much less obvious in those teeth devitalized after the arrival of the disease.

But one all-important fact will not permit the acceptance of the theory of Paul Dubois or that of Josipowici, viz, the fact that pyorrhea begins at the neck of the tooth, and not at its apex.

But if the primary lesion of the disease were to be localized in the tooth or in the pulp, then the most advanced lesions of pyorrhea—or, at least, their maximal appearance—should be found at the apex, which, as we know, is contrary to all clinical observations and to the data furnished by pathological anatomy. Later we shall dwell more at length upon this particular point.

Consequently, if these pulpal and dental modifications are very real, and are due, perhaps, to the same general causes as pyorrhea, they are without influence upon the development of the disease, and are simply synchronous with, but independent of, pyorrhea.

(2) *The cementum.* Likewise we shall discard the theory which would place the primary lesion in the cementum (Howard Stewart). Indeed, if some cemental lesions accompany the evolution of pyorrhea, these are always infinitely less marked than those of the pericementum and of the osseous tissues.

Again, as can be seen from the sections of Hopewell-Smith, cemental lesions, which constitute a hyperplasia of that tissue, are especially marked at the apex; and we shall make, in regard to this, the same observation that we have just made apropos of the pulp, *i.e.* that pyorrhea begins at the neck of the tooth, and apical cemental lesions are incapable of explaining the development of pyorrhetic lesions. It is all the more necessary to see in this cemental hypertrophy either a modification analogous to that of the dentin, of which we have just spoken, or an echo of the inflammation of the periodontal ligament which accompanies the development of pyorrhea.

(3) *The alveolo-dental ligament.* The lesions of the alveolo-dental ligament, or

pericementum, are constant in the mature stage of the disease, and in the opinion of a number of authors who adopt the viewpoint of Magitot, pyorrhea alveolaris is an inflammation of the alveolo-dental ligament occurring in certain individuals predisposed by an arthritic diathesis. Thus Peirce, Kirk, Endelman, and several others make of pyorrhea a gouty localization in the pericementum, analogous to other articular localizations of gout, by deposits of uric acid or its salts in this ligament.

Before discussing the nature of the pericemental lesions, we must say a few words upon the most recently expressed theories regarding their production. Endelman* has published a very interesting paper upon this subject in which he gives the following explanations of urate deposition:

Urates are soluble in alkaline and precipitated in acid solutions. The salts of uric acid resulting from faulty metabolism, *i.e.* incomplete oxidation of nitrogenous foods, are in solution in the blood by virtue of the alkalinity of this fluid.

Now, in a state of rest, or of slight activity, the articulations, ligaments, synovial sacs, cartilages, and articular liquids have an alkaline reaction, but in the state of activity this reaction is changed into one of lowered alkalinity (relative alkalinity) or, very rarely, into a distinctly acid reaction.

The deposits of uric acid salts in the ligament would, then, be due to an abnormal activity of the alveolo-dental articulations.

These salts would thus be deposited in the articulations, where they would crystallize, and where, according to C. N. Peirce,† they “would act as specific irritants and engender the well-known phenomena of pain, congestion, tumefaction, exudation, faulty nutrition, disorganization of the tissues, formation of pus, osteomyelitis resulting from resorption of the alveolar process, and finally loss of the

*J. Endelman, “Le Problème de l'Acide urique dans ses Rapports avec les Inflammations périécementaires,” *l'Odontologie*, 1908, vol. xl, p. 289; and see also Endelman, *DENTAL COSMOS*, 1908, vol. 1, p. 1076.

†C. N. Peirce, “Pyorrhée alvéolaire: Un Manuel de Dentisterie Opératoire de E. C. Kirk,” adaptation française par R. Lemièrre, p. 489.

teeth—phenomena characteristic of pyorrhea. The most usual seat of deposition of these salts is at the apex of the root, where the structure of the alveolo-cemental membrane is least dense, least resistant, and most voluminous.

G. V. Black* localizes the seat of pyorrhea in the glands which he has described in the pericementum; but these, it appears, are nothing else than the peridental epithelial débris described by Malassez (1885). In a solitary case observed by him he believes himself to have found these pseudo-glands gorged with micro-organisms. Kirk† adopts the ideas of G. V. Black, and thinks that by virtue of their embryonic character, these pseudo-glands have a lowered vitality and lessened resistance to infection. They would, thus, constitute the *locus minoris resistentie* of the peri-radicular membrane.

According as the infection of these were superficial or deep, there would be either a purulent discharge between the cementum and its covering membrane, with formation of a purulent pocket, or a suppuration through the tissues terminating in the formation of a gingival fistula at some distance from the free border of the gum, and thus determining what is designated by the term pericemental abscess upon a vital tooth.

The theories which have just been given in *résumé* are evidently most seductive, but in this subject we cannot be content with simple imaginings or more or less ingenious deductions. These theories must be in accord with observed clinical facts, upheld by pathological anatomy.

The theories just reviewed, however, do not appear to conform to these conditions: it is easy, indeed, to raise objections to these theories which I consider unanswerable.

* G. V. Black, (1) "A Study of the Histological Character of the Periosteum and Peridental Membrane." 1887: (2) "The Fibers and Glands of the Peridental Membrane, DENTAL COSMOS, 1899, p. 101.

† E. C. Kirk, "The *Locus Minoris Resistentie* in Pyorrhea Alveolaris," DENTAL COSMOS, 1913, p. 577.

Thus, the theory of the deposition of salts of uric acid (Endelman) rests entirely upon the articular hyper-activity of the teeth, but if we examine these facts from the general point of view we shall at once see that they are contrary to the data furnished by clinical experience, which show that gout develops only among those individuals whose physical activity is lowered. Doubtless, it might be argued that in pyorrhea it is only a question of the articular hyper-activity of the teeth, a hyper-activity which cannot have any effect upon the general nutrition. But outside of this particular point, the theory of Endelman cannot be in accord with clinical facts, for pyorrhea is seen to develop not in teeth which are most exercised, which would be in conformity with this theory, since their articular tissues are less alkaline, but, on the contrary, pyorrhea affects more particularly the teeth least exercised. It develops with remarkable frequency in teeth completely deprived of antagonists, which, being continually in a state of rest, would have their articular surfaces always in an alkaline medium.

If teeth affected with pyorrhea are improved, and are even cured, when they are immobilized, this is not because they are no longer exercised, but exactly to the contrary, because they are more exercised. Indeed, a tooth affected with pyorrhea, if it is loose, serves either not at all or only very slightly for mastication, by virtue of its mobility and its accompanying sensitivity; while, on the contrary, when it is immobilized by a ligature or splint, it becomes firm and can be used for mastication.

A tooth deprived of its antagonist, if it is firmly connected with other teeth by a bridge, is thus forced to be of use indirectly in mastication, and the pyorrhea is ameliorated. These are the facts, in absolute contradiction to the very attractive theory of Endelman.

Not only is this theory not justified by observed facts, but even strong doubt must be cast upon the existence of uratic deposits, which appear to be rather a simple imaginary concept than a tangible reality. All authors who have desired to

investigate these calculi, not by the aid of theoretic deductions, but with microscopes and chemical reagents, have been led to conclude either that they are non-existent,* or, in least unfavorable cases, that their rarity is equivalent to a negation in the presence of a disease so widespread as pyorrhea alveolaris.

In the interesting discussion which followed Endelman's communication to the Odontological Society of New York,† W. B. Dunning said: "The important question is to know if the concretions found upon the apical portion of the roots are in reality salts of uric acid." Dr. Endelman, citing the researches of Kirk and others, considered that as admitted; while the observations of Talbot, made upon a great number of cases, seem to permit a doubt in this respect. In his chapter upon uric acid as an etiological factor he concludes as follows: "Out of 950 cases examined by different chemists at different times, 5-6 per cent. gave positive results in regard to uric acid, on chemical and microscopical examination. These results demonstrate positively that interstitial gingivitis is not due solely to uric acid; this substance is only an expression of the uric acid diathesis, and a coincidence; for it is not always present in the gums and tartar of patients attacked by gout or those with the uric acid diathesis.

If, then, the presence of the gouty diathesis at the origin of pyorrhea is uncontested in the large number of cases, yet it does not follow that uric acid must play a direct and simple rôle in the development of the disease.

If uric acid plays a rôle in the production of pyorrhea, it is more reasonable,

* M. Galippe, with the aid of two chemists, MM. Brun and Goullard, has in vain sought for the presence of uric acid in the saliva and in fresh tartar upon the teeth of pyorrhetics. Nash says that the occurrence of a true tophus upon the roots of teeth is an absolute impossibility; the differences between the tophi and radicular deposits are so essential that it is inconceivable that they ever could have been confused. (Julien Tellier, *loc. cit.*, p. 55.)

† DENTAL COSMOS, 1908. *l'Odontologie*, 1908, vol. xl, p. 357.

as E. S. Talbot thinks, to consider it, not as a mechanical irritant, in the form of salivary calculi, but rather, through the medium of the circulation, as a toxic chemical irritant to the cellular protoplasm, and as thus injuring the vitality of the cells of the alveolo-dental tissues.

Regarding the theory expressed by G. V. Black and by Kirk, which localizes the initial lesion of pyorrhea in the pseudo-glands—which are, as we have said, the periodontal epithelial débris of Malassez—this theory does not conform to the data furnished by pathological anatomy, if we consider articles presented by Hopewell-Smith and by Mendel Joseph. If these epithelial masses play a rôle in the development of lesions of the radicular ligament, it is only at an advanced period, when, according to the description given by Roemer, "the periodontal ligament, infiltrated by small round cells, is transformed into a granular tissue (granulomatous), analogous, it seems, to fleshy buds,"* and it is at this period that the periodontal ligament is invaded by epithelial masses in the form of a wedge or cone.

This description of the lesion of the alveolar ligament at an advanced period of the disease confirms the excellent description given by Malassez in 1885.† But except G. V. Black, who has only one case to support his theory, no other investigator has been able to confirm the considerable rôle which this author assigns to this epithelial débris.

Mendel Joseph, whose anatomical-pathological works upon pyorrhea are very noteworthy, has sought, in a recent study, to verify Black's ideas, to which Kirk has brought the support of his theoretical deductions. Joseph‡ has arrived at conclusions diametrically op-

* Julien Tellier, "La Pyorrhée alvéolaire." p. 21; O. Roemer, "Periodontitis und Periostritis alveolaris," *Handb. d. Zahnheilk.*, 2d ed., vol. ii.

posed to those of these two authors, which I could not do better than to quote:

Starting with the idea of justifying the hypothesis of our eminent American *confrères*, I arrived at the point of having to express a completely different opinion. Not one of my preparations, and many of them were clear demonstrations, permitted me to recognize in the glandular body of Black a tendency, or peculiar predisposition, to fix the infectious agent in the course of the pyorrhetic process. My observations have led me to conclude that the epithelial débris of the peridental membrane (I do not here refer to the epithelial débris scattered through the gingival tissue) is stifled and destroyed by the formidable influx of leucocytic infiltration, even before micro-organisms can reach it.

Thus the theory of deposits of uric acid salts in the pericementum, and the theory of epithelial rests, that of Black, cannot be accepted, if we may depend upon clinical observation, chemical researches, or microscopic examination.

(4) *Pericemental abscesses upon vital teeth; their nature.* To justify the analogy of pyorrhea alveolaris with the development of gout, the most frequently invoked fact is one observed in a rare form of the disease, characterized by the formation of alveolar abscesses upon vital teeth, which evolve in part as abscesses due to pulp death. The pulps of these teeth are vital, the gum appears to be intact at the necks, and these abscesses appear to form on the middle of the roots, without other apparent communication with the outside than a fistulous opening at the surface of the gum.*

* A tooth exhibits the symptoms of acute apical pericementitis: a bistoury passed into the apex of the swelling over the root may give vent to a glairy, mucus-like discharge, or, in some cases, pus flows. A further examination may reveal the loss of underlying alveolar wall: on exposing the root, which is partially denuded of pericementum in this area of denudation, the presence of a calculus is detected. The pulp responds to tests for its vitality, and the gum margin and marginal pericemental attachment appear to be intact." (Henry Burchard, "Varieties of Dental Calculi," DENTAL COSMOS, 1898, vol. 1, p. 8.)

Kirk* describes the observed symptoms thus:

The clinical phenomena attending the evolution of this condition are in general those of other inflammations of the pericemental membrane, but modified somewhat as to their violence. A slight uneasiness about the root of the affected tooth is first felt, followed by increasing tenderness to percussion, slight extrusion of the tooth from its alveolus, increasing pain of a dull, throbbing character, localized swelling which does not become diffused over a large area, no tendency to the infiltration of surrounding tissues, no burrowing of pus into adjacent territory; and finally, localization and pointing of the abscess and evacuation of the inflammatory products upon the gum surface at a point close to the inflammatory focus.

To explain the formation of these abscesses, whose nature has hitherto appeared very difficult to determine, a number of authors affirm that it is a question of gouty tophi of calcium urate, which was deposited upon the root by the medium of the circulation, and which determined an abscess by infection through the blood stream. It was seen above that in Kirk's opinion these abscesses are the result of the invasion of Black's pseudo-glands through the blood stream.†

Having had occasion to observe some of these cases, whose pathogenesis is so obscure, and having been able to establish absolutely its real etiology, it seems to me to be worth while to insist partic-

* E. C. Kirk. "Abscesses upon Teeth with Living Pulps," DENTAL COSMOS, 1898, vol. 1, p. 621.

† [In the paper quoted by Dr. Roy I merely suggested as a possibility that pericemental abscesses might result from hematogenous infection. In a later paper I called attention to Black's observation of the direct infection of the epithelial rests of the peridental membrane through the gingival tissues, an observation which clearly determines the modus of infection in pericemental abscess as well as in pyorrhea alveolaris, which, though differing in clinical expressions, are pathologically identical.—EDWARD C. KIRK.]

† E. C. Kirk, "The Locus Minoris Resistentiæ in Pyorrhea Alveolaris," DENTAL COSMOS, vol. IV, 1913, p. 577.

ularly upon a point which has not yet, to my knowledge, been brought out, and which reduces to *nil*, in the cases observed by me, the deductions in favor of the gouty tophi. Cases of this sort are very rare; a number of experienced practitioners have never encountered one. The first case which I had occasion to observe upon a maxillary first incisor, fifteen years ago, made a vivid impression upon my memory. Having been unable to find any other plausible explanation, I was not far from giving credence to the theory of the formation of the gouty tophus in the pericementum, without communication of the alveolar articulation with the exterior. Nevertheless my mind was unsatisfied, and some years later, having had occasion to see a similar case, I examined and explored the tooth in question with the greatest care, and was rejoiced to find the explanation of the fact which had so greatly troubled me.

The patient was a woman of sixty years, an arthritic whom I had been attending for some time. She still retained all her anterior teeth, as well as her premolars. Her teeth were firm, in spite of the few light attacks of pyorrhea in the region of two premolars. One day this patient came to see me, with a vestibular abscess half a centimeter above the margin of the gum of an upper lateral incisor, an abscess absolutely analogous to those currently observed in the course of complications resulting from pulpal death and putrefaction. Yet the tooth incontestably had a living pulp, as its sensitiveness was very clearly shown in response to cold and heat. No apparent communication existed between the abscess and the gum margin. The tooth was not loose. The obvious conclusion seemed to be that it was a pericemental abscess of gouty origin, without previous communication of the alveolar articulation with the exterior. In default of a better explanation I was about to accept this conclusion, when, with a fine probe, while carefully exploring the abscess through the small gingival fistula to gain some idea of its form, I perceived that this vestibular ab-

scess arched down over the proximal surface of the tooth and appeared to be directed backward in the direction of the palate. I then examined this region with greater attention. On this side it did not appear to have any apparent lesion. Around the tooth the gum appeared healthy. There was no recession, there was no suppuration; but what was my surprise, in passing my probe to the palatine part of the neck of the tooth in the region diametrically opposite the seat of the abscess, to see that my instrument sunk into a narrow but deep pocket extending toward the threshold of the vestibular abscess along the proximal surface of the root at about its middle third, a communication which I easily established with a fine probe.

It was, then, a question, contrary to all first appearances, of a pyorrhetic abscess, analogous to those which we commonly have occasion to observe, having its origin in a pocket open to the exterior but opening at a point apart from the opening of the pyorrhetic pocket.

It remained to establish the reasons of this peculiar evolution of the abscess. These reasons I found in the interlocking of the teeth of my patient. She had, indeed, an overbite; that is to say, in a state of occlusion her maxillary incisors completely covered those of the mandible, which impinged upon the palatine mucosa exactly at the neck of the second incisor, at the point where the pyorrhetic pocket opened, closing the mucosa over the orifice of the pocket. As a result of this, the products of infection and decomposition not being easily able to make exit through the natural orifice—the movements of mastication forcing them, on the contrary, deeper—had sought an exit at a distant point of lessened resistance—that is, toward the vestibular region.

The establishment of this fact was, for me, a ray of light as to the nature of the trouble in the first patient whom I had observed, and in whose case I had not been able to establish the true origin of the abscess; for I remembered very clearly that that patient also presented a marked overbite, and that the same

pathogenic conditions might have been present in the production of the phenomena whose true origin I had mistaken.

I have since had occasion to observe two other similar cases, one with my *confrère*, V. E. Miégeville, of Paris; and in all the cases of pericemental abscesses upon vital teeth that I have observed, the patient had an extensive overbite.

Naturally, I cannot maintain that all similar cases mentioned in the literature had an origin analogous to that of the cases that have come under my own observation; but the facts which I have adduced upon this subject show that it is necessary to be very careful in expressing a definite statement as to the nature of observed phenomena.

I am convinced that if anyone desires to undertake a detailed investigation of so-called pericemental tophic abscesses upon living teeth, he will find an analogous as well as completely natural explanation of their production; and he can determine in principle that pericemental abscesses upon vital teeth are pyorrhetic abscesses formed in a serpiginous pocket, whose opening at the neck of the tooth is obscured by reason of the location of another opening at a distant point on the gum.

(5) *Interstitial gingivitis*. According to Talbot, the initial lesion is present, not in the alveolar ligament, but in the interstitial connective tissue of the gums, whence the name, interstitial gingivitis, which he gives to the disease. From the interstitial tissue the inflammation is said to extend to the alveolar ligament and to the alveolus. These different tissues would be, according to him, adventitious and transitory organs, undergoing modifications determined by a precocious senility of the dental organs.

The lesions described by Talbot do not appear to me conformable to those described by the most recent works on morbid anatomy, all of which fail to recognize any particular lesion of the interstitial connective tissue, which, according to this author, is the seat of the initial lesion of the pyorrhea. Furthermore, I no more believe that this hypothesis is completely in accord with clinical observation and the logical evolution which it appears to me ought to be assigned to this disease.

On the contrary, I am completely in harmony with the idea of a precocious senility as the cause of the disease, as claimed by Talbot, and later I shall return to this particular point.

(To be continued.)

The Principles Governing the Construction of Permanent Fixatures in the Treatment of Pyorrhea Alveolaris: With a New Method of Construction.

By Dr. KARL ELANDER, Göteborg, Sweden.

IN the title of this article there appears a term which, as far as I know, has not previously been used in dental literature, viz, the word *FIXATURE*.

By this term I wish to indicate *such apparatus or appliances as are used for the fixing, stabilizing, and immobilizing of teeth which, through pyorrhea alveolaris, have lost their normal stability and firmness in the alveolar process.*

Presumably on account of the fact that this therapeutic method, especially in its more general application, is of relatively recent date, one has hitherto had to be content with more inconvenient and complex terms, such as fixation apparatus, pyorrhea retainer, pyorrhea retention, and similar unwieldy terms. In America the term "splint" is also used to designate such apparatus. The specific signification, however, of this latter term, meaning an expedient in cases of broken bones, makes the use of the term for dental cases unsuitable. I have therefore thought it more appropriate to use the term "fixature," of Latin origin, as being more in analogy with the word "ligature," which is already used in orthodontia.

Although we hope that in the near future pyorrhea patients will, as a rule, come to us for treatment during the early stages of the disease, it must be acknowledged that at the present time we are far from this goal.

In the majority of cases the patients are totally unaware of having been attacked by the disease, and become cognizant thereof only when it has reached such an advanced stage that one or more

teeth have become seriously loose. This symptom is but too often just the one which at last attracts their attention, and compels them to apply to the dentist for help.

In other cases the patients really have noticed alarming symptoms for years, but on consulting the dentist have received the not very cheering answer that there is nothing to be done in the matter. That the general dentist in the past has usually taken this position toward pyorrhea may be pardonable, in a way. Now, however, when we have specialists who are capable of bringing about a healthy condition—and this the more surely the earlier the case comes under treatment—it seems to me that every general dentist who will not himself undertake the treatment of pyorrhea alveolaris should feel it his imperative duty to send the patient to a specialist, as he does in the cases of malocclusion and oral surgical operations.

But even if such a custom should promptly come to be adopted, we could nevertheless not hope to reach in a reasonably near future the state where advanced cases of pyorrhea would not very often be met with, and we must therefore not cease to make the therapeutics of the advanced stages a subject of special study.

The authors on the subject are unanimous as to the usefulness of the fixature in the treatment of loose pyorrhea teeth. Some authors go so far as to not only consider the fixature to be of secondary significance, but even to declare that it possesses a direct healing effect.

In accordance with this belief we find as recently as 1909 in the DENTAL COSMOS a long, enthusiastic article by Houston⁽²⁰⁾, entitled "Immobilizing as a Cure for Pyorrhea Alveolaris."

Undoubtedly there is ground for the belief that, if not an entire cure, at least a powerful help to that end may be achieved by the fixation of the teeth. We all know that rest, partial or total, is a most valuable expedient in therapeutics. Nevertheless, I must add that the fixture should not be relied upon in the treatment of pyorrhea alveolaris as the sole means of bringing about a cure.

Fig. 1 illustrates a case where the disease was cured without applying a fixture. The radiograph shows that the

Fig. 1.

disease was very far advanced when I began the treatment. The right central incisor was denuded up to the apical region, and the right lateral and the left central had lost their alveolar support up to the middle of the root. At the time of photographing the teeth were so loose that the patient could not brush them, and had to be content to cleanse them with pieces of cotton. The gums were swollen and bled easily, and there was present a never-ceasing flow of pus. The patient was unable to bear the expense of a permanent fixture, and for some time, therefore, the teeth were fixed with silk ligatures. These, however, showed a tendency to force the teeth from their normal positions, and had to be given up. By degrees we finally succeeded in getting the better of the disease, and the patient has managed without silk ligatures or any other

kind of fixation for two years. Although the teeth are still very loose, they are fit for service and are otherwise sound.

For all that, it is my opinion that a permanent fixture would be very useful to the patient at this time. A permanent fixture produces an exceedingly comfortable sensation of security and rest in the mouth; the patient need no longer be cautious in the movements of the tongue and lips, but is now able to move them freely.

At the first sitting I apply a temporary fixture, which does service until the suppuration has ceased, and the gum has become fairly normal; then I apply the permanent fixture.

THE THREE ESSENTIAL REQUIREMENTS OF A PERMANENT FIXTURE.

I wish to lay down the following three principal requirements of a rationally constructed permanent fixture:

(1) It must be of such construction that devitalization of the pulp is unnecessary.

(2) It must effect a permanent stability of the teeth.

(3) It must satisfy the demands of mouth hygiene.

A secondary, though not unimportant requirement is that the demands of esthetics should be considered, in so far as is compatible with the fulfilling of the three principal requirements.

(1) AVOIDING DEVITALIZATION OF THE PULP.

Concerning the first principal requirement, viz, avoiding devitalization of the pulp, opinions, as expressed in literature, have differed in a most radical manner, and at present there is little doubt that the adherents of the kinds of fixtures which require devitalization of the teeth are in a decided majority. It is not so many years ago that a large group of ardent adherents maintained the dogma that the devitalization *eo ipso* was a particularly advantageous therapeutic expedient in the fight against pyorrhea alveolaris, and one which, independently

of the need for fixation, should be practiced on all pyorrhetic teeth. As recently as 1912 Mamlok⁽¹⁴⁾ expressed this opinion without any reserve. The belief was that through the removal of the pulp the periodontium would be enabled to utilize the blood supply from the arteries which otherwise supplied the pulp. Though this argument to me seemed very faulty, and much the same as if a surgeon, who could not get an injured finger to heal rapidly enough, amputated a sound finger next to the injured one in the hope of thus making use of the sound finger's blood supply. Nevertheless, because of the repeated assurances as to the beneficial results obtained by this method I was tempted to try it in one case. The result was absolutely negative.

So far from the extirpation of the pulp being a benefit to the diseased periodontium, it is, on the contrary, an obvious danger even though both the tooth and its entire surroundings be perfectly healthy. Our actual knowledge of the apical conditions establishes without contradiction the fact that every tooth without a pulp is a permanent *locus minoris resistentiæ*.

In pulp extirpations and root-fillings the first requirement is that we do not ourselves cause infection, and second that we succeed in hermetically closing the apex. Should we fail as to the first requirement, then we have from the beginning created a dangerous seat of infection, whether we close the foramen or not—and who dares to say that he absolutely closes the foramen? But even if we succeed in this, the possibility is always present that the apex may become infected in a hematogenous way.

Rosenow⁽²¹⁾ has now shown that even rather harmless streptococci, such as *streptococcus viridans*, if debarred from oxygen supply, evolve into pathogenic bacteria of high virulence. Further, it has been shown that these streptococci are able to penetrate into the bloodvessels, and, preserving their virulence, may lodge in some narrow capillary in the heart, kidneys, or other organs. There they cause metastatic abscesses, which

may prove fatal, and at best may cause considerable disturbance with accompanying depression and suffering.

An abscess at the apex of a tooth root means a daily depression, the importance of which is evident from the large number of authenticated cases presented where diseases in other organs, which have been suspected to be connected with an apical seat of infection, have healed quickly after the apical infection had been removed, and this although the diseases had previously defied even the most painstaking treatment. Ottesen of Christiania once showed me a patient who had been blind in one eye, and had been referred to him by an eye specialist. An apicoectomy was performed for this

FIG. 2.

patient, and little by little the sight returned.

Under such circumstances I do not hesitate to contend that the devitalization of a sound pulp is a worse crime than the one of placing crowns on untreated roots. The latter case constitutes a reprehensible omission, but in the former case we directly *cause* a pathogenic condition.

Fig. 2 shows a very common and very illustrative case. The crowns are perfectly sound, the disease is not extremely far advanced, though the teeth are rather loose. Who dares to say that, with a view to stabilizing the teeth, we are justified in bringing about in this case five *loci minoris resistentiæ* in a jawbone which in the corresponding apical regions is quite sound. If some day the patient should become affected with

one or perhaps several purulent granulomas in this region, could he not with very good reason reproach us for a treatment, adverse to the teaching of science, which unnecessarily caused him this injury and its possible sequelæ in the form of heart or kidney diseases, etc.?

It is bad enough if such things happen through want of knowledge, but it is much more deplorable when dentists deliberately reckon with this risk, and attempt to justify their methods of procedure by thinking they may correct any subsequent trouble by performing an apicoectomy, not taking into account the possibility that an apicoectomy may be resorted to only *after* a kidney or some other important organ has been injured. Such reasoning seems in any case as un-

FIG. 3.

ethical as when a physician who, in vaccinating a patient against smallpox happens to transfer syphilis to him, consoles himself with the thought that syphilis may be healed by means of salvarsan. No medical man has the right to treat a patient in such a manner that the latter thereby contracts an illness, when it is at all in the power of the physician to avoid such an occurrence.

Moreover, apicoectomy means such a great loss of root substance that it should be avoided as long as possible, even by the dentist who is shortsighted enough to limit his range of observation only to the strictly local field of pyorrhea alveolaris.

In Fig. 3 the root of the central incisor is already denuded more than half-way. The pulp was devitalized—which, by the way, caused the patient pain for several days. The extirpation

was extremely laborious, and not until a labial trephining had been performed did it prove in some degree successful. But the radiograph shows that an apical pulp fragment was left, and this continued to live and to retain its sensitiveness. It was impossible to remove it,

FIG. 4.

although every possible way was tried. Finally we decided to attempt to devitalize the fragment with sulfuric acid; but to no avail. In order that no one may think that I treat my patients too roughly, perhaps I should state that the patient in this case was *myself*. This case proved to be very instructive to me. Shortly afterward a granuloma de-

FIG. 5.

veloped—also seen in the illustration—which was only discovered by chance when I tried my new roentgen apparatus on the tooth. Thanks to the devitalization, I then had to submit to an apicoectomy (as patient), which proved to be a particularly valuable experience.

It is not beneficial to the tooth, however, to be deprived of nearly half of its

already insufficient root portion. (See Fig. 4.) And in spite of the fact that part of the jaw-bone beneath the apex has since formed anew, and that the tooth has been immobilized by means of a fixture, the tooth is to this very day, the fourth year after the operation, sensitive when biting, and has a diminished functional power.

Fig. 5 presents a case where an apicoectomy is out of the question. Here the sockets are atrophied entirely down to the apex, and the connection of the tooth with the jaw-bone is effected by little else than the pulp. An apicoectomy here would thus be equivalent to exodonty, and devitalization *per se* would undoubtedly mean a breaking-up of the continuity between the tooth and the periodontium.

The experienced pyorrhea practitioner knows that even in such extremely advanced cases the few remaining fibers of connective tissue perform their duty to the utmost, with an admirable faithfulness. Several years ago I managed to persuade the patient in question to allow me to apply a permanent fixture to her teeth. Before that she had managed to make out for some ten years with provisional arrangements, in spite of the fact that she is without occluding molars, and is therefore compelled to put a double burden of mastication on her incisors. The patient has an unconquerable aversion to artificial teeth. Her pyorrhea is now subsiding in a satisfactory manner, and all the pulps are thriving nicely, which is manifest by the hyperesthesia of the root surfaces.

Moreover, the preservation of the pulps secures the important advantage to the teeth of keeping them more elastic and transparent, with no risk of discoloration. There is no doubt that, on the whole, a tooth loses more or less of its power of resistance to pathogenic insults and mechanical damages after having lost the pulp. Further, it is my firm conviction that the very fact of maintainance of the pulp in a vital condition is of powerful assistance in our fight against pyorrhea alveolaris itself. The extirpation of the pulp creates at

best a cicatrix at the apex; but cicatricial tissue is always of less value than normal tissue, both as regards its functional capacity and as to its faculty of nourishing itself. On the other hand, it is quite evident that the bloodvessels of the living pulp offer possibilities of compensating, to a certain degree, for any superpressure on the diseased periodontium. The apical regions are supplied by end arteries, which do not branch off in any other direction but to the pulp.

Finally, it should be remembered that the devitalization in itself is very unpleasant to the patient.

(II) PERMANENT STABILITY OF THE LOOSE TEETH.

I now come to the second principal requirement of the fixture, viz, that it must permanently stabilize the loose teeth. This requirement implies that the fixture must possess a certain rigidity, that it must not be springy, and must not yield or bend under moderate strain. Otherwise the fixture cannot stand the strain of mastication, and its connection with the teeth to be stabilized will inevitably be impaired.

The points of connection between the fixture and the teeth are already in themselves points of weakness. It is therefore very important that their number be not too small and, above all, that they be not situated all on the same level, as is the case where silk or metal thread fixtures are employed. In such a case the fixture, even though it were perfectly rigid, would not be capable of keeping the teeth immobile for any length of time. The teeth would act as regular levers, with either the apex or the point of connection as the fulcrum. We have all seen teeth which, although they have been fixed to absolute stability in a correct line by means of a silk thread have after some time become deranged.

Suppose we let three sticks, which at one end are movably fixed, represent as many teeth, we shall find that if we bind together their other ends by means of a horizontal plane, the swinging circle will

still be considerable. If we attach to the sticks another horizontal plane, the mobility will be reduced to nearly naught, *i.e.* the sticks will be immobilized. The more horizontal planes we attach, the more will the stability be increased.

This experiment shows how desirable it is to have the connection between the teeth and the fixture effected by as many horizontal planes as possible; in other words, that the areas of connection shall extend as much as possible in the direction of the longitudinal axis of the tooth.

It may be that the hope of bringing this about has led to the devitalization of the pulp with the aim of using the root-canal for anchoring the fixture; or perhaps this practice originated from the use of the pivot tooth, whence it has been transferred to the bridge, and thence to the fixture.

However, if we look into the matter a little more closely, we shall find that the anchorage in the root-canal does not necessarily provide in a satisfactory way for the need of extended areas of connection in the direction of the longitudinal axis, as these areas of connection should function in all directions of the transverse axis, in order that the aim be gained. Now, if we regard Fig. 6, reproduced from the work "Die Alveolar-Pyorrhoe und ihre Behandlung," by Neumann, we find that the distance from the occlusal limit of the fixture to its apical limit at the end of the root-pin is considerable. But we must not forget that this distance is of significance only as regards the masticatory insults to which the tooth may be exposed from the labial region. As to all insults from the approximal or lingual regions, the root-pin alone will have to bear the pressure, because, in order to use the root-canals with due observance of the necessary parallelism, the fixture must be so constructed that at the crown it rests against the lingual surfaces solely. The lower incisors, however—a group of teeth which, as we know, is most often in need of being fixed—receive the largest pressure labio-occlusally. The consequence is that it is here, first and

foremost, that we should have a mechanical anchorage, and by no means, at least not *solely*, in an apical direction. The catch-phrase coined by Rhein that "The center of gravity of the fixture is to be located in the root-canal," is altogether incorrect, if "center of gravity" is to be

FIG. 6.

interpreted as meaning the point of anchorage. If the main anchorage is placed in the root-canal, then, on account of the law of levers, its extension must be made longer. We know too well that this is not always possible along the lower incisors, and from Fig. 6, which we may consider a typical case, this is evident.

A third consequence of the demand for stability is the desirability of anchoring the mobile tooth or group of teeth to two firm neighboring teeth, preferably situated at each of the two extreme points of the fixture. Even when it is a question of stabilizing only one small central incisor, this method of attachment is the most advisable. In some specific cases the supporting teeth may be chosen in the row of the supported ones, but preferably not. As, for technical reasons, it is particularly difficult to attach a fixture which comprises more than six teeth, one may in extreme cases, if all the six should be loose, be justified in omitting firm supporting teeth from the fixture. If these teeth are in a curved line, they become perfectly immobilized by the rigid fixture, in spite of their various degrees of looseness, for the reason that the teeth and the fixture form one coherent block.

The position of a body is determined, and is invariable, if it has at least three fixed points so located that the lines connecting them form a triangle. The experiment with the three sticks referred

FIG. 7.

to above illustrates this. Fig. 7 shows six extremely loose upper incisors made perfectly immobile without the assistance of firm supporting teeth.

(III) FULFILLING THE DEMANDS OF MOUTH HYGIENE.

The third requirement of the permanent fixture is that it shall be so constructed that it neither prevents nor makes particularly difficult the cleaning of the teeth. The fixture must not create extra recesses, which harbor food and collections of mucus, and which may be inaccessible not only to the brush and the toothpick, but also to the dentist; it therefore must not rest close against the gum, thus rendering impossible or unreasonably difficult access to the root surfaces in case a future scaling should be necessary. The fixture should everywhere face the mouth cavity with smooth and flat surfaces. It is unnecessary to enter upon this phase of the subject in a detailed manner.

ESTHETIC REQUIREMENTS.

Finally, the fixture, in so far as it is compatible with the previously formulated principal requirements, must also

be constructed with regard to the demands of esthetics.

This demand is of more or less secondary importance, and not a general one. As to the posterior teeth, it may be totally disregarded, and as to the incisors, the demand does not always assert itself in an equal degree. Not infrequently the incisors are concealed behind thick lips and sometimes bushy mustaches, so that the incisors can scarcely be seen, particularly the lower ones. When, however, these teeth are clearly visible and particularly outstanding, esthetics must necessarily be considered. For instance, we should only in very exceptional cases be able to persuade such a patient to have the labial surfaces of the incisors covered with an all-gold fixture.

On the whole, however, I think one is justified in saying that the esthetic point of view in most cases becomes, in a way, of secondary importance, even when the teeth are fully visible. The necessity for a fixture is seldom met with before the patient is of a fairly advanced age, forty or fifty years or more, when he feels a greater interest in keeping the teeth in a good functional state than in a beautiful outer appearance. Besides, the teeth attacked by pyorrhea have already greatly detracted from the facial appearance for years, partly because the gum recedes, making the teeth appear abnormally long, and partly because the position of the teeth becomes abnormal when the ligamentum circulare is no longer there to keep them in normal position.

As Fig. 8 shows, broad and disfiguring diastemata arise, and the teeth protrude more and more. Shakespeare, the discernor of man, noticed this condition, and not knowing its cause, supposed it to be a symptom of senility. In one of his plays he says of a woman, "She is no longer young, because her upper teeth are already protruding."

In spite of such symptoms the patients have, by some sound instinct, abstained from sacrificing their diseased teeth on the altar of beauty. If there is a chance that the teeth may be re-

stored to a healthy condition and to working power, the patients in the majority of cases do not demand that the fixture be perfectly invisible, but will permit a fairly extended liberty of action.

HISTORY OF THE DEVELOPMENT OF FIXTURES FOR PYORRHEIC TEETH.

Before I venture to present my own method of solving the problem of the fixture, I think it would be well to review the literature, in order that we may form an idea of the development of the subject and its actual status. I must,

possible to obtain chronological data on all of them, and I therefore prefer to enumerate them in groups according to the leading principles of construction.

I shall first refer to the following constructions, each of them being an example of its group, and possessing only an historical interest:

Quedenfelt⁽¹³⁾ simply makes an ordinary rubber plate which clasps the lingual surfaces of the teeth, and likewise covers the occlusal surfaces.

The second is a method referred to by Warren⁽²⁾, without mentioning the originator's name. This construction consists of a gold fixture made in one

FIG. 8.

however, previously remark that I have not had an opportunity to make such a review as thoroughly as I should have wished. Nevertheless I think it probable that I have succeeded in including in the review practically all the published types of construction, at least if I may judge from the mutual references of the authors.

Having laid down as the most important principle that the fixture must not require the devitalization of the pulp, I need not here refer to such constructions as do not fulfil this condition. Besides, the fixtures of this kind are the most commonly known and used, and it is therefore the more unnecessary to enter upon any description of them.

With regard to constructions which do not require devitalization of the pulp, I have found not less than twenty-one more or less alike. It has not been

possible to obtain chronological data on all of them, and I therefore prefer to enumerate them in groups according to the leading principles of construction.

The following group is characterized by the fixture being mainly applied at the occlusal edges of the teeth:

As early as 1888, Rhein—later the originator of the devitalization fixtures—stated in the DENTAL COSMOS that he had succeeded in immobilizing teeth by applying to the occlusal surfaces a platino-iridium wire which was fixed in position by malleted gold fillings.

The author has in one case effected a fixture by making cohesive gold fillings in the edges of the teeth. In spite of the extreme looseness of the teeth the fixture functioned for some years.

Bryan⁽¹³⁾ applied a gold wire to the edges of the teeth. Small pins were soldered to the wire, which fitted into a short groove, cut in the direction of the longitudinal axis of the tooth.

Cohn⁽⁸⁾ modified this method by sinking the gold wire down into a mesio-distally running groove, provided the edge of the tooth was broad enough; if not, he made the groove behind the edge.

FIG. 9.

Bruhn⁽⁸⁾ places this apparatus a bit farther in the lingual direction, so that the grooves of attachment are located behind the pulp. None of the fixtures included in this group give sufficient stability.

FIG. 10.

The fixtures of the next group consist of rings or bands around the teeth, soldered to each other in different ways.

Bryan⁽⁹⁾ (Fig. 9) applies the rings at the gum edge. For hygienic reasons this method must be rejected.

Herbst⁽¹²⁾ (Fig. 10) seems to have modified the method of Bryan in so far that he does not close the rings, but makes them overlap as on a key ferrule. A certain elasticity is thereby effected, which, it is true, facilitates the attach-

FIG. 11.

ing of the rings to the teeth, but which also further impairs the hygienic conditions, and lessens the stability of the fixture.

Burchard⁽¹⁾ (Fig. 11) makes the ring or band narrower, and applies it at

FIG. 12.

the middle of the crown. The extension of the connecting surface in the direction of the longitudinal axis is here too small to establish the required stability.

Sachs^(7, 11) (Fig. 12) removes from Burchard's rings the greater part of the

labial section, whereby the appearance but not the stability profits. He states that the originator of this appliance is Case, who many years earlier described it, but only used it as an expedient for retention after orthodontic treatment. In the pyorrhea literature this method is therefore named the Sachs-Case method.

Sachs points out that the stability may be increased, partly by allowing the cuspids to retain the ring complete, and partly by applying gold crowns on the first bicuspids. The appearance does not profit by this modification, and the improvement in the anchoring of the fixture gained from the supporting bicuspids does not eliminate the danger of the incisors gradually working loose, as their areas of connection with the

FIG. 13.

fixture are too small in the direction of the longitudinal axis of the tooth.

This objection holds also concerning the modification originated by Thiersch⁽⁹⁾ (Fig. 13). He anchors the fixture by means of pins in the root-canals of the canines, and the method is thus appropriately to be classed among the group requiring devitalization.

Michel⁽¹¹⁾ has attempted to increase the stability of this appliance by having the interstitial parts running out in the labial direction in the form of round knobs; on to these he fastens a transverse band of celluloid.

We now come to the last group, viz, fixtures whose main part consists of a lingual plate or a lingual transverse band which is fastened to the teeth in different ways.

The most primitive of these is the method of Resch⁽¹²⁾ (Fig. 14), which consists of a cast lingual plate and a

cast labial bar, fastened to each other by means of screws passing through the interstices.

G. Marshall Smith describes in the DENTAL COSMOS for the year 1900 an apparatus of the same type, with a modification consisting of bars, which have been substituted for the more slender transverse bands, obtained by polishing gold foil strips against the teeth of a plaster model, and then strengthening the strips by means of solder.

Fish⁽³⁾ retains in the labial transverse band only the parts facing the interstices. These parts are respectively fastened to the lingual plate by means of screws. The last three methods violate hygienic demands.

A method referred to by Warren, without mentioning the name of the originator, seems to be at least equally

FIG. 14.

advantageous from an esthetic viewpoint. The lingual plate is here furnished with holes corresponding to the interstices, and through these holes gold wires pass around the teeth.

Warren⁽²⁾ (Fig. 15), in his turn, develops this idea so far as to maintain the gold wire ligatures only around the four incisors, but attaches the plate to the cuspids by means of a knob pin, which fits into a hole bored in the lingual sides of the teeth mentioned, and facing labially.

Neither of these two methods can be said to obtain sufficient stability to enable the fixture to function permanently.

According to Warren, Trueman⁽²⁾ had several years earlier recommended a lingual bar, on which were soldered a row of small pins, extending in the labial direction, and fitted into pits drilled horizontally into the center of the upper part of the crowns. Threads were cut

in the labial part of the pin, and the lingual plate was screwed to the teeth and secured by nuts.

Witkowski⁽¹⁰⁾ drills pits of the same character as Trueman's, but splits the pins at their labial ends and rivets them by means of specially constructed riveting pliers, so that the split ends are turned at right angles and secured in small transverse grooves.

Mosessohn⁽¹⁶⁾, who operated with Witkowski's method, found the demand for parallelism of the pits too difficult to realize, and therefore only solders two

FIG. 15.

of the pins. After having attached the bar, he passes the remaining pins through both bar and grooves, and contents himself with riveting them to both the labial and lingual sides. Even if there were not occasion for well-grounded doubt as to the stability and strength of the preceding fixture, this modification certainly means a further deterioration. Witkowski's fixture is objectionable also for the reason that it creates interproximal recesses for harboring food contrary to the demands of hygiene.

Bruhn⁽¹¹⁾ (Fig. 16) secures the lingual plate by means of small pins extending in the direction of the longitudinal axis, and anchored in grooves bored behind the pulp. This I think

it is possible to do only exceptionally, and at any rate the stability of the fixture will be too unreliable with so frail an anchorage.

Rygge⁽¹³⁾ sinks the lingual transverse band down into grooves cut transversely

FIG. 16.

into the lingual sides of the teeth, and to afford further anchorage, he uses small pins soldered to the band and fitting into corresponding holes. This fixture is recommended only for the upper incisors. Its small extension

FIG. 17.

longitudinally will not, I think, procure sufficient stability.

Lastly, Burgess⁽¹⁸⁾ (Fig. 17), as late as December 1915, mentions in the DENTAL COSMOS a fixture which requires great manual skill. As the figure shows, it consists of a lingual plate, composed of cast gold inlays soldered together, one

for each of the lingual surfaces of the teeth to be stabilized. In these, steps are cut, the appearance of which the figure shows more clearly than I can describe. Two small pits are drilled longitudinally in the cervical wall of the tooth on each side of the pulp. The gold inlays are provided with corresponding pins, which thus, together with the ledge-shaped notches, form the mechanical anchorage of the fixture. Against this fixture it can be said that the surfaces of anchorage possess too small extension longitudinally. Besides, the pins must be kept too slender, and finally, the enormous difficulty of preparing from four to six notches and from eight to twelve fine pits, maintaining due parallelism, must be taken into consideration.

Some years ago I set to work at the problem of stabilizing, and not feeling satisfied with the solutions which the literature presented, I at first formulated the above-mentioned three principal requirements. Gradually I came to understand that those demands involved the following points of observation as to the details of construction:

(1) The material must possess sufficient inherent rigidity to stand the strain and wear of mastication. The consequence is, that only metals may be taken into consideration, and our experience concerning metals in the mouth limits us immediately to cast gold. Platinum and aluminum might perhaps also be considered, but the former cannot be cast, and must be used in the form of sheet metal, which is objectionable on account of its springiness; the latter metal is not sufficiently strong for the purpose.

(2) The connection between the fixture and the teeth must not be made in a direct way, for the reason that in spite of the best adaptation, nooks and corners for harboring food are created, at variance with the demands of hygiene; and also because the stability of the fixture will be of a mechanical nature only. The fixture must therefore be attached to the teeth in the same manner as gold inlays, *i.e.* by means of

a thin intermediate layer of cement. There must be no deviation from the rule that the fixture *must be* of cast gold. We see daily that not even the most excellent adaptation of shell crowns can obviate caries—simply, according to my opinion, because of the springiness of plate gold, which by degrees opens a space between the gold, cement, and tooth, and allows fluids of the mouth and bacteria to enter.

(3) Simplicity is a further important desideratum. It is obvious that the greater the number of parts, loose screws, pins, metal ligatures, etc., the fixture is composed of, the less rigid it will be as a whole, the different points of connection constituting as many points of weakness. For this reason the fixture should be made in one continuous piece.

(4) Constancy in form is the next requirement of the fixture. It must not possess tiny projecting parts or edges or weak points of any kind which might yield to mechanical strain during use. Thus there should be no riveted pins or tongues bent to the tooth.

(5) Further, the fixture must be attachable as a whole in its correct site. It is sufficient if the application can be made from one side only, which also from the viewpoint of stability is the most advantageous.

(6) Connecting surfaces of the greatest possible extension, especially in the direction of the longitudinal axis, are of the utmost importance, as I have already pointed out in the beginning of my article. Devitalization being excluded, such surfaces must be chosen on the crown. Pins such as suggested by Burgess make the work more difficult to perform than is warranted by the stability effected by such means. While as a rule, as we know, it lies beyond the limits of possibility to effect an absolute immobility in relation to the jawbone—even the most powerful and sound molars show by their approximal grinding facets that there is present some movement—the strain must in the long run be too great to be met only by two short, slender pins on each side of

the pulp of a lower incisor. I do not think anyone should even consider applying a gold inlay, with an anchorage such as Burgess proposes, to a lower incisor or a canine which, for instance because of abrasion, has only the lingual half of the crown left. (Such cases are met with sometimes, as we all know.)

In consequence of this reasoning, I decided to abandon all kinds of anchorage by means of pins.

There remained then only the external surfaces of the crowns. Of these I found I could be satisfied with three, viz, the lingual and both the approximal surfaces, if only I ground the plane of the approximal ones so that they would converge mutually in a labial direction,

FIG. 18.

and form acute angles with the lingual surface. A transverse section of a tooth thus treated shows the form of a salmon's tail. (Fig. 18.) The tooth is clasped on three sides by the fixture, while the open labial side is smaller than the opposite lingual one, and therefore excludes the possibility of the tooth becoming loose from the fixture in the labial direction, provided the fixture is not springy.

A fixture of this shape can therefore only be applied to the teeth in the direction of their longitudinal axes. The fixture is kept from sliding down below its proper place by the lingual surface, which gives the tooth a greater thickness cervically than occlusally.

Considering the question from this point of view, it would seem best to grind all the approximal surfaces parallel. As this, however, with our present resources, presents too great difficulties, I grind the teeth in such a manner that the approximal surfaces of each tooth

diverge toward the root. Consequently, the cervical portion of the interproximal space is made longer than its occlusal portion, but not as broad.

The strength of the attachment of the fixture to the teeth is greater and more stable in proportion as the surfaces of connection are extended in the longitudinal direction (Fig. 19). In this respect experience early taught me to be content only with the best. However, the cervical limit of the fixture toward the lingual surface should not be placed below the hindmost point of the tuberculum linguale, and on the approximal surface the limit should not extend as

FIG. 19.

far as to the enamel edge, but stop a little bit above it. In both cases access to the pyorrhea pockets would be rendered unnecessarily difficult, if a future scaling be needed. If the approximal surfaces be ground in such a way that the limits extend to or below the enamel edge, a larger labial surface would have to be sacrificed than would be compensated for by the increase in longitudinal extension.

The interstitial portions of the tooth toward the labial side are carefully shaped in such a way that they replace as perfectly as possible the approximal portions ground away. I give special attention to making narrow notches from the occlusal portion down. Thereby the impression is given that each tooth has been restored with gold fillings, and no one suspects that this visible gold is part of one continuous

piece. On the lingual surface interproximal notches are cut toward the gum, thereby facilitating cleansing.

hours of intense labor to removing fixture pins from loose pyorrhetic teeth can readily appreciate this advantage.

FIG. 20.

FIG. 21.

FIG. 22.

A fixture of this kind affords easy access to all the root surfaces for the removal of accretions, and allows the patient to keep his teeth clean as easily as previously, nay, in reality with even

In an article to come I propose to describe the technique of making this fixture, and shall describe some methods which experience by degrees has shown me to be practical.

FIG. 23.

FIG. 24.

FIG. 25.

greater ease, because the stability of the fixture admits of a considerably more energetic brushing.

With regard to the serviceableness of this fixture in practice, I might state that to date I have applied a score or more, and all of them to the full satisfaction of my patients as well as to my own. The first one I made in January 1914. It is still, after four years, in the best condition.

A not inconsiderable advantage of this fixture over the root-canal pin fixture is the greater facility with which it may be removed should that be necessary. The dentist who has sacrificed

Non-cohesive Gold.

By L. ASHLEY FAUGHT, D.D.S., Philadelphia, Pa.

(Read before the Academy of Stomatology of Philadelphia, May 16, 1918.)

AT the May meeting of the Academy in 1913, there was read, or, more properly described, delivered with oratorical effect, one of the most remarkable papers which it has been the pleasure of this or any other society to hear. It was, as set forth in the announcement of the meeting, "A Plea for the Use of Non-cohesive Gold." (See DENTAL COSMOS, 1914, vol. lvi, p. 705.)

I had the honor to be one of those requested to open the discussion. What I then said was hardly a specific consideration of this material for filling teeth, but, as one who has been in the practice of dentistry long enough to be in personal contact in my younger days with the "fathers," who at that time

were skilled in the use of this valuable material, it seems fitting to embrace this opportunity to follow up the good work of Dr. Sweeney by a further consideration of non-cohesive gold.

It is just possible that I may be the repository of some practical information, which will be presented on this occasion. It is certainly not at this date a hackneyed topic, but do not from this remark deem it not a practical subject, for non-cohesive gold has been used exclusively by most eminent practitioners, and judgment passed upon it by them as "the only material with which a permanent filling should be made."

To begin with, let us definitely understand what non-cohesive gold is. Often

we learn best what anything is by knowing what it is not.

Non-cohesive gold is not simply unannealed gold; it cannot by annealing be made cohesive. One of the inherent and peculiar characteristics of gold in a state of absolute purity is cohesion. Beyond these statements all is inferential and speculative.

In the early days of dentistry, 1835, non-cohesive gold was non-cohesive gold, and no confusion arose, as there was no other form of gold used for the purpose of filling teeth. In the decade from 1850 to 1860, the cohesive quality was recognized in the "sticky" foils, as they were termed. That which was really its first and innate quality appeared, and the question arose as to what produced the non-cohesive quality—a query, so far as the profession is concerned, that has never been fully answered. For years and years the firm of Abbey & Sons made and supplied to the profession a strictly non-cohesive gold. The making of this particular brand was the secret of that firm, and seems to have died with the death of the makers. I have used and still have in my possession some of this good old-time non-cohesive gold foil. The making, however, of a pure non-cohesive gold is not a lost art, though only a few gold foil manufacturers know how it is done, and those who know are not disposed to reveal the secret. A very good quality of non-cohesive gold foil is extant today, and while the users are few, it is still in my opinion a valuable material for saving teeth, and as such, I think should be more generally used. I hope that dentistry will not let its use become a lost art.

I may be pardoned if I assume to mention here the names of the present-day makers. The S. S. White Dental Mfg. Co. makes an excellent non-cohesive gold foil; so do Morgan & Hastings of Philadelphia, and I think, though I have not handled any of late, that the firm of Hood & Reynolds, Boston, produce it also. There is, too, on the market what is known as Swift's non-cohesive foil. This last-named product is a little

thinner in the sheets than the others, and the weight used should be No. 5 or No. 6. It can be obtained from Hart & Friend of Baltimore. If pressed for an opinion as to preference I may say that the best workers with non-cohesive gold today are inclined to feel that the product of the S. S. White Co. is very close in working qualities to the old Abbey foil, which was a non-cohesive gold in fact as well as in name.

As to the manner of using non-cohesive gold. The knowledge is current that it is to be used on the wedge principle. Primarily, this means that each cavity is to be filled with cylinders or ropes of non-cohesive foil, standing on end on the bottom of the cavity, and protruding slightly above the orifice. A wedge-shaped instrument should then be forced down through the center of this mass of gold, and the gold crowded toward the lateral walls, making an opening into which other cylinders are to be placed until the cavity is again full. The process of wedging is repeated again and again until it is impossible to make further entrance and further introduction of gold. Surface condensation is then made, and the filling completed by careful burnishing.

It is evident that this lateral pressure implies the necessity for resistance. Non-cohesive gold is, therefore, to be used in all simple cavities, and in all positions in which such cavities occur. It may, however, be used either wholly or in part in nearly all compound cavities having three walls, provided two of these walls are parallel. In all cases the walls should be strong and solid, with solid edges. Sharp angles should be avoided as well as deep undercuts; retaining pits are unnecessary. It is important that the depth of the cavity should be greater than its diameter. The gold should be prepared in cylinder form for each case, remembering that the larger the pieces can be worked the better will be the result. I shall not assume to describe the method of preparing cylinders, believing that those whom I have the honor of addressing are fully competent to do this, and have,

through long usage in the handling of gold, become past-masters of this technique.

Perhaps a further word is necessary to more completely outline the application of the wedging principle in making these fillings. The wedge must be recognized as having almost unlimited lateral condensing power, and the instrument used should never be permitted to come in contact with the walls of the cavity, except at its base. Commence the insertion of the instrument into the mass of gold with a small sharp instrument, and increase the opening by using a little larger point, and so successively until lateral condensation is thoroughly accomplished, the opening made always reaching to the bottom of the cavity, for it is quite important that the cylinder now inserted to fill up this opening should, like all the other cylinders used, stand upon the base of the cavity. Condensation is made at first lightly with a coarse plugger; then firm pressure is made with a finer plugger. These pluggers should be slightly serrated. By this procedure a uniform, solid surface will be assured.

The procedure described applies to the filling of simple cavities with non-cohesive gold foil. It is assumed that compound cavities will not be attempted until the dentist has acquired consider-

able skill in the use of this pliable material; then his knowledge and tact will come to his aid, and make such operations easier. The principle is the same in each, but the form in which the material is used may be varied by the use of narrow mats as well as cylinders.

These cavities usually open from the crown of the tooth, and include one of the approximal surfaces. The filling is to be commenced by covering the floor of the cavity with mats or cylinders projecting into the approximal opening. Condense these thoroughly against the cervical wall. The lateral walls can then be treated in the same way, and the remainder of the cavity filled with mats a little wider than the vertical depth. In finishing, all fillings should be trimmed to the edge of the cavity, and no overlapping of gold permitted.

I claim no originality for the matter here presented to you this evening, for to me, and perhaps to some others here, it seems as "old as the hills;" but I have seized upon the opportunity to again place on record for those of the younger generation a consideration of a material which I trust may again be brought into general use.

MEDICAL ARTS BLDG.

[See also *Discussion*, as reported under "Proceedings of Societies," this issue.]

Hemorrhage and Its Treatment.

By WM. FRANCIS DREA, D.M.D., Colorado Springs, Colo.

(Read before the Colorado Springs Dental Society, Colorado Springs, Colo., March 11, 1918.)

HEMORRHAGE is a general term used to designate any escape of blood from a bloodvessel. It usually comes about as a result of injury, but certain cases may result from disease, as in scurvy or purpura.

Depending upon the vessels involved, we may classify hemorrhage as arterial, venous, and capillary; also as (1) primary, happening at the time of injury; (2) intermediate, within twenty-four hours, during the reaction period; (3) secondary, after twenty-four hours, and usually happening a week or ten days after the injury. This may be the result of sepsis, slipping of a ligature, or of failure of tissue to repair.

Hemorrhage may cease as a result of natural means. Natural cessation of bleeding results from coagulation of the blood, which increases with length of flow, from lowering of blood pressure, from weakening of heart action, as in syncope, and from retraction and contraction of the walls of the vessels, this condition being more pronounced in the arteries than in the veins.

When the bloodvessels are too large to contract spontaneously, bleeding may be controlled by pressure applied proximally to the injury when the artery is involved, and distally when the vein is concerned. Ligation of the vessel on both sides of the wound should be resorted to, and where this is impossible the main artery should be exposed and ligated at some point between the wound and the heart. Most of the smaller arteries require only seizure by the hemostatic forceps, when crushing of the intima permits of clotting. Normally, cap-

illary bleeding may be checked by means of moderate pressure applied against sterile gauze placed over the injured area.

Bleeding from the very small vessels and capillaries may be checked by other means, such as cold; hot water at temperature between 120° and 150° F.; elevation of the part; styptics or astringents applied locally, such as tannic acid and glycerin, perchlorid of iron, adrenalin solution, and the cautery. In addition to these agents are the biochemical hemostatics introduced during the last few years, of which more details will be given later.

FACTORS CONCERNED IN COAGULATION OF BLOOD.

According to Howell, five factors are concerned in the coagulation of blood—prothrombin, antithrombin, fibrinogen, calcium salts, and thromboplastin. These are all normally in the plasma except thromboplastin, which is contained in all the tissue juices as well as in the platelets. When the blood escapes, the thromboplastin from the platelets and tissue juices neutralizes the antithrombin, thus permitting the prothrombin to become thrombin. The thrombin in the presence of calcium converts fibrinogen into fibrin. Many investigators have accepted this theory as being correct, though Morowitz has advanced one somewhat similar that is advocated by some, but into the details of which we will not here enter.

All of the factors in the coagulation of blood, or any of them, may be altered in disease, and when this occurs we get an alteration in the coagulation time.

USE OF BLOOD SERUM.

The value of blood serum as a hemostatic is unquestioned, and human, horse, and rabbit sera have been successfully used. The coagulation has been hastened by intravenous injections. Local application of fresh serum also hastens coagulation where it has been delayed. Anti-diphtheritic serum may be used until fresh serum is prepared, though it is not so effective.

There are disadvantages in the use of serum, however: Comparatively large quantities of foreign protein are injected at the same time which have nothing to do with coagulating the blood; it loses its coagulating power soon; there is danger of anaphylaxis and of other disagreeable results, and there is also delay in its proper preparation which may be harmful in emergencies.

Hess succeeded in separating the coagulative factor in serum from the non-coagulative. He found the euglobulin to be the active principle. This hemostatic contains 2 per cent. protein, and is more potent than the whole serum, containing 6 to 7 per cent. of protein.

THROMBOPLASTIC SUBSTANCES.

Hess has prepared a solution and suspension of ox-brain in physiological saline with 0.3 per cent. tricresol as a preservative. It is known as thromboplastin. He recommends it for local use in the bleeding of the newborn, nasal hemorrhage, and in the parenchymatous bleeding associated with various hemorrhages. Where local applications fail it should be injected into the site of bleeding, as in hemorrhage after tooth extraction. It can be diluted and boiled. It is innocuous by the mouth in considerable dosage, and may be of value in gastro-intestinal bleeding. Hess has also noted that it possesses healing qualities. A baby of five days had hemorrhage as the result of incision of the frenum of the tongue. Blood serum and whole blood had been injected subcutaneously, and local applications of silver nitrate and tannic acid had been made without success. Bleeding persisted for two days

in spite of all efforts. Thromboplastin solution was applied locally with partial success; then a few cc. of the solution, previously boiled, were injected into the site of the hemorrhage and the bleeding stopped at once with no recurrence. Hess also regards it as almost specific in true hemophilia.

Cronin has reported on the results obtained by the department of Health in the City of New York with the use of thromboplastin solution following adenoid and tonsil operations performed by different operators. Previous to the introduction of thromboplastin solution into these clinics, injection of horse serum before operation was performed as a prophylactic measure, followed after operation by another injection of serum, if bleeding had not ceased within a reasonable time. Now thromboplastin solution is used on a mop, which is pressed on the denuded surface, and bleeding is controlled at once. It has been used in 2036 adenoid and tonsil operations, and there has not been a single case of bleeding since this has been made a routine of practice. No cases of illness or bad after-effects occurred, though the solution must have been swallowed in some cases. "Thromboplastin is safe, effective, and easily applied."

KEPHALIN.

Another biochemical hemostat has been prepared from brain tissue. It is a brain lipid extracted by ether. Cecil followed the method advised by Howell for making kephalin from the brains of hogs. Also he used gauze impregnated with kephalin after surgical operations. This gauze was prepared by him as follows: "The kephalin is dissolved in excess of ether, about a 5 per cent. solution being made, and this concentrated kephalin solution is poured over gauze strips six feet long and six inches wide. The packs are then folded, rolled, wrapped in two muslin covers and sterilized in the steam autoclave at a temperature of 120° C. for ten minutes." This heat does not interfere with the coagulation action of the kephalin. After using this

gauze there was very little bleeding, and much less tense packing was necessary. Cecil uses it a good deal in urology; it is to be preferred to iodoform gauze. His conclusions are as follows: (1) Kephalin causes a quicker and firmer clot. (2) Not as much pressure in packing is necessary as when plain or iodoform gauze is used. (3) When packs are removed, the clot is of sufficient firmness to prevent bleeding. Hirschfelder is quoted as finding kephalin of great value in bleeding from bone, though he uses a less pure preparation of kephalin.

Other substances have been prepared, such as "coagulen ciba," an extract said to be prepared from blood platelets. The originator of this preparation is Fonio. Coagulens has been used in Germany and praised highly. Parke, Davis & Co. manufacture "coagulose," a soluble powder obtained by precipitating normal horse serum. A clot of leucocytes prepared by R. Gregoire and H. Mondon proved excellent for promoting local coagulation.

TREATMENT OF HEMORRHAGE.

Ordinarily, capillary oozing will cease of itself. But in hemophilia and the different forms of purpura the flow of blood may continue, even to a fatal result. For this reason, before operation, careful questioning as to history, individual and family, should be made. Also the coagulation time of the blood should be determined.

Hemophilia is inherited, manifesting itself in the males only, though transmitted by the female. It is not common in this country. In Switzerland and certain other parts of Europe it is found more frequently. There is little positive evidence that a lack of calcium salts exists.

In the various forms of purpura we also have prolonged bleeding. Purpura may be caused by certain drugs, circulation of bacteria or their toxins through the bloodvessels, jaundice, Bright's disease, chronic alcoholism, the so-called blood diseases (such as leukemia, anemia, scurvy) and generalized malignant diseases.

The cause of purpura simplex is not known, though it probably could be found if a bacteriological examination of the tonsils or the gums in cases of pyorrhea alveolaris accompanying it were made. The purpura hemorrhagica is especially dangerous, as profuse hemorrhage may occur from the nose, mouth, or bowel. Hess states there may be a definite hereditary purpura. There are usually purpuric skin lesions as well. There is a marked diminution of the blood platelets, prolonged bleeding-time, and a normal or slightly delayed, rarely much delayed coagulation time, also a non-retractile blood-clot that is usually soft. Purpura hemorrhagica may be an idiopathic disease or it may appear as a symptom secondary to some recognized disease, as pernicious anemia, lymphatic leukemia, diphtheria, tuberculosis, etc. Probably the fibrinogen is subnormal in amount or quality.

In hemophilia the blood platelets are normal in number; in purpura hemorrhagica they are diminished. It is known that where platelets are fewer than 60,000 per cubic millimeter the bleeding time is prolonged, and spontaneous bleeding usually occurs. When the count is below 20,000 bleeding always occurs. Constriction applied to the arm as in venesection will produce petechiae.

Duke has pointed out the importance of a blood platelet count in studying those conditions in which an irritant like a chemical or bacterial toxin has entered the blood stream.

Weil insists that it is possible to detect non-coagulation or excessive coagulation by determining the coagulating power of the blood. He advises inquiry as to personal and family history with respect to hemophilia, thrombosis, phlebitis, etc., and tests the coagulation time of blood by distributing the blood in tubes of uniform caliber. This is sufficiently instructive for the purpose. Further information can be derived by pricking the ear with a lancet and counting the minutes before bleeding stops spontaneously. Taking up the successive drops on a blotter, hemostasis oc-

curs normally in from $2\frac{1}{2}$ to $3\frac{1}{2}$ minutes. When tests show excessive coagulation of blood there is danger of thrombosis, and ether and chloroform are to be avoided, as these injure the blood. Injections of blood serum and loss of blood may induce thrombosis in this case.

For more accurate determination of coagulation time there are the methods of Duke, Boggs, and M. Block. The advantage of determining the coagulating power of the blood lies in the fact that operation may be postponed to the time most favorable for it and proper preparation made.

After operation one of the biochemical hemostatics such as kephalin or thromboplastin solution should be used as a matter of routine. There are no advantages in using chemicals, and several disadvantages, such as destruction and sloughing of tissues, with increased risk of infection.

Swallowing of coagulating agents has no systemic influence on coagulation of blood. The agents must be locally applied or injected. There is little positive evidence that calcium is lacking in hemophilia. Weil has no confidence in calcium chlorid, whether given by the mouth or injected. In most pathological cases there has been no diminution in the calcium content of the blood. The calcium content of the serum is not increased even when large amounts of calcium salts are injected. The serum of normal individuals contains from 9 to 11 mg. of calcium per hundred cubic centimeters. Less dependence should be given to the use of calcium in prolonged bleeding, as its value is questionable. There are a few cases, though, as in hematomogenous jaundice, eclampsia, pneumonia, and particularly uremia, where distinct decreases in amount of calcium are noted.

The various factors concerned in coagulation should be borne in mind, and the treatment will naturally suggest itself. There should be no stimulation until all bleeding has ceased, and then only when it is necessary. The patient should be kept warm by artificial means. After hemorrhage has ceased the patient

should be treated as any other anemic individual.

CONCLUSIONS.

(1) Possibility of hemophilia or purpura should be considered, and coagulation time of blood determined.

(2) Surgical hemostasis of larger vessels should be brought about.

(3) Where local application can be made to the bleeding area one of the above-described biochemical hemostatics should be used, as after tooth extraction, oral, nose and throat operations, etc.

(4) They may be used to clear up the bleeding field during operation.

(5) The biochemical hemostatics should be injected subcutaneously previous to operation where a hemorrhagic diathesis exists, those hemostatics being chosen that can be boiled without losing their activity.

(6) Where there is danger of thrombosis or where the coagulating power of the blood is excessive the biochemical hemostatics should not be injected.

(7) Chemicals should not be used as hemostatics when the biochemical hemostatics may be secured.

(8) Less dependence should be placed on the use of calcium salts and gelatin.

402 BURNS BLDG.

A Comparison of Office Policies, with Special Reference to Pulp Exposure or Death.

By OTTO E. INGLIS, D.D.S., Philadelphia, Pa.

(Read before the Academy of Stomatology of Philadelphia, May 16, 1918.)

THE dental profession is now face to face with conditions that are to the mind of the writer the outcome of policies definitely pursued by dentists or by their patients with the tacit consent of the dentist. That these policies have been pursued in ignorance, on the part of both dentists and patients, as to the gravity of the outcome, in no wise lessens the difficulties to be faced.

The difficulties lie in the presence in the mouths of a vast majority of people, who have more or less regularly employed dentists—some of them very regularly according to their own accounts—of devitalized teeth numbering from one to eight or ten, with their complications of possible abscesses. Some of these teeth have been well treated mechanically, and perhaps aseptically, or more probably antiseptically, and are without abscesses or granulomas at the apices. Some have been well treated in so far as the root is well filled, or even

overfilled, while radiolucent areas are to be found. A much larger number have been only partially treated, while the canals have been easily susceptible of better filling. In many of these there are no abscesses, in some there are.

It is not the writer's intention to go into the merits of root-canal work, but to endeavor to state reasons for there having been a necessity for root work at all. It is obvious that, leaving out consideration of anchorage and bridge work, fixed or removable, in which devitalization was intentional, canal work has been necessitated by pulp exposure or close approach. Why have so many cases of this sort occurred?

There are two answers: (1) The patients have waited too long before consulting the dentist, and have then usually done so because of pain. (2) The dentist has overlooked or neglected cavities existing at the time of examination, and the patient has departed in

full confidence of safety, only to suffer a surprise in an attack of pain which again takes him to the dentist.

For the first fault the remedy is education of the *clientèle* before the evil is done; such education as shall convince them that "consultation" early and often is the only method of avoiding serious cavities or pyorrhea alveolaris. The writer has talked this to his patients year in and year out, and is convinced that something more than talk at the chair is necessary to carry conviction even to those who desire to save their teeth, and believes that the time has come for a persistent campaign of education along the indicated line.

Articles should be published at frequent intervals in the daily or other publications expounding repeatedly the dangers of delay, and pamphlets dealing with various phases of dental disease and with the care of the teeth in general should be distributed to all patients, so that the knowledge shall become widespread in each community. It is by no means intended that these shall take the form of personal advertising, but be authoritative matter issued under the name of local, state, or national dental societies without even the name of the writer attached. This will involve expense for the societies in so far as the publication of the pamphlets is concerned, and the societies should be allied in this work, bearing their *pro rata* share according to membership. Outside dentists should also contribute, as it will be equally to their advantage to escape the evils of the ignorance of patients. The pamphlets in condensed form should be published by one or more societies under its or their names, and sold to individual dentists at as near cost as possible for free distribution to the *clientèle* of that dentist, and under ethical agreement. At the present time the public is getting its education largely through personal experience of individuals published in magazines.

In the second case, in which the dentist is at fault, a brief *résumé* of policies employed may be of some benefit.

There is, first, the dentist who, having

complete control of his patients, orders them to return at frequent intervals, sufficiently close for at least that form of prophylaxis which keeps cavities to a minimum size, and allows no large ones to form except as an occasional and unavoidable accident. While perhaps not so impeccable as strict monthly prophylaxis, it is still a commendable policy. Whether this dentist employs the policy of strict extension for prevention in all cases of small approximal cavities is a question to be left to individual judgment. The point at issue is that no pulp exposures shall be allowed.

There is, second, the dentist who pursues the policy of filling only cavities which can be extended readily into large contours. A well-known dentist who enjoys a highly paid practice once remarked to the writer that he paid no attention to very small cavities, but saw his patients every three months, filling such cavities as in his judgment required filling. No criticism is made if he comes within the limit of safety, but the writer is convinced that such a policy will in nine cases out of ten lead to pulp exposure, and even worse, to pulp hyperemia and death under well-made fillings. Pyorrhea can of course be prevented if the dentist takes pains to observe and treat gingival irritations.

The third class of dentists pursues the policy of attending to such work as is demanded, making little effort to control regular attendance, but such work as is done is well done, and with some effort to complete the work in each mouth. Many exposures are treated, and many pulps die after effort at salvation.

A fifth class keeps the patient in continual attendance, has the office full of patients, places medicated cotton in cavities, and suggests a return next Thursday. Small and usually cash fees are exacted, though in the end the patient pays the price in money, time, and destroyed teeth. One dentist of whom the writer knows has thus earned the sobriquet of "Spit and go home," owing to his habit of spending a few minutes on

each patient and invariably making that remark. One of his patients is said to have thus spent a year and a half in having one tooth treated, though possibly some slight filling of smaller cavities was done.

The writer would finally enter a plea for frequent prophylaxis, and more especially for thorough cavity diagnosis and filling, for upon the latter much depends. It is not so easy as it seems to diagnose small approximal cavities; even the electric lamp is of no avail in many cases.

In one typical case the writer, upon complaint of the patient, separated two teeth with Perry separators, and found two approximal cavities with tiny orifices facing and closing each other; then allowed the teeth to resume their positions, and directly afterward, and with full knowledge of their presence, was unable to find them with lamp or explorer.

Even the late Dr. Miller wrote in his textbook that he had seen a number of patients, presumably of excellent dentists, who had consulted him regarding large cavities which he thought had developed during a transatlantic voyage. Without doubt they existed, but were not discovered, before the voyage was begun. Even many occlusal cavities which should be filled are neglected, and

frequently the ends of fissures are not extended.

Even with the best intentions and most rigid control of patients, we may be unable to prevent an occasional exposure, but from experience the writer is convinced that such a policy is the only one that can be considered safe and sane at the present day. While it is not orthodox operative dentistry, the writer is firmly of the opinion, based upon twenty years of experience in earing for a considerable number of patients from childhood to adult life, that the strict filling of small approximal cavities as such, conjoined with other prophylactic treatment at short intervals, of say three times a year, is much superior to orthodox contour approximal work carried out because of the presence of larger cavities seen at longer intervals.

It is perfectly true that repairs are at times necessary, and even replacements required, but in the main the teeth are as well saved without pulp exposure, and are of better appearance. As before stated, however, no objection is taken to the preference for extension if, in the judgment of the particular practitioner, this be advisable.

WEIGHTMAN BLDG.

Interpretation of Roentgenograms.

By THOMAS B. WADE, D.D.S., Philadelphia, Pa.,

INSTRUCTOR OF ROENTGENOLOGY, EVANS DENTAL INSTITUTE SCHOOL OF DENTISTRY
UNIVERSITY OF PENNSYLVANIA.

(Read before the Academy of Stomatology of Philadelphia, Pa., Thursday evening,
March 21, 1918.)

I DO not know that I have anything new to offer with regard to the interpretation of roentgenograms, but before taking up that subject I want to make a few remarks on the question of which should come first, the clinical diagnosis or the X-ray diagnosis. I know that the pendulum is swinging too far toward the tendency to depend almost entirely on the roentgen diagnosis. This was illustrated to me recently when a member of the profession sent a case to me to have films made of the entire mouth. When the dentist saw the films he said, "This is not what I want; I am very much disappointed." I asked him what he had expected to see, and after some hesitation he replied that he expected to see pus showing yellow, blood-vessels red, etc., and that he had also expected to get a full diagnosis and prognosis of the case. This instance only shows how far the pendulum is swinging in the wrong direction.

One should never attempt to make an X-ray diagnosis without first knowing the full history of the case. The clinical diagnosis should always precede, and should be confirmed or rejected by the X-ray diagnosis. The roentgen ray gives us a picture in the anatomico-pathologic sense only, and was never intended to give us the true pathological findings of the case. It is only an aid in our diagnosis, and is efficient then only when it is supported by a good knowledge of anatomy, histology, and pathology, together with a full history of the case. Or in other

words, "The X-ray is a part of the physical examination, not a method to supplant it; it is an extension of our faculties of sight, not a substitute for clinical diagnosis or the tactile sense; it is an analysis of different tissue densities, not a chemical reaction, and it records certain gross pathologic changes but does not seek to take the place of the microscopic slides or the culture tube." (Crane.)

FIG. 1.

The roentgen analysis is quantitative rather than qualitative, and the roentgen map is accurate for boundaries but indefinite for specific names. The X-ray diagnosis of root-canal work, fractures, and foreign bodies is final. The time may come when we may be able to learn new signs or when we can find new meanings in old signs; or we may have reached the limitation of specific signs on the plate or film. Again, the X-ray does not reveal to us whether there is pus or granulation tissue present. The accessory sinuses in normal condition are filled

with air, and anything displacing this will readily be shown by the X-ray.

Before attempting to make a diagnosis of any pathological condition we should know how the tissues appear under normal conditions. Fig. 1 is a normal case.*

The radiability of the tissue is as follows:

Radioparent.. { Skin.
Mucous membrane.
Pulp.
Peridental membrane.

The shadow cast by these tissues is black, owing to the fact that they offer no resistance to the rays.

Radiolucent.. { Bone.
Dentin.
Lamina dura.
Enamel and pulp stones
if present.

The shadow cast by these tissues is light, from the fact that they offer slight resistance to the rays. The enamel is the most radiopaque part of the body, owing to its high percentage of calcium salts.

Radiopaque.. { Metal fillings.
Shell crowns.
Bridge work.
Root-canal fillings, with the
exception of plain paraffin.

The shadow cast is very light, because these materials are impervious to the rays.

The radiability of common substances is as follows:

Radioparent.. { Pure hydrogen.
Air.
Celluloid.
Aluminum.
Cardboard.
Wood.
Flesh.
Rubber.

The shadow cast is black.

Radiolucent.. { Barium.
Bismuth.
Calcium.
Bone.
Teeth.

The shadow cast is light.

Radiopaque.. { Steel.
Lead.

The shadow cast is very light.

For my part of the program this evening I have chosen to show you the sequel of diseases of the dental pulp. We know that there are two varieties of pathologic changes which take place in the pulp; first, a suppurative inflammation ending in an acute alveolar abscess, and characterized by pericementitis, swelling of the soft parts, and formation of pus which burrows in the line of least resistance and collects under the periosteum or gum. One would think in a case of this kind that a great abnormality would show on the film, but such is not the case, owing to the fact that no destruction of the bone has taken place. After the pus has drained, if the lesion is not taken care of, the abscess passes into the chronic stage, and in time a dark area can be seen, as I shall show later.

Second, a proliferating pericementitis, or the granuloma, which is symptomless. This is an inflammatory growth and can usually be diagnosed by the X-ray, but in a dense mandible the area is not so well defined. The film of a granuloma shows a clearly circumscribed area or an abrupt line of demarcation between the dark area and the surrounding tissues. (Fig. 2.) For experimental purposes the root end of the lateral (A) was amputated and the granuloma was found to be intact. The molar (B) was extracted and the granuloma was found to be intact at the root-end. According to Thoma granuloma is caused by the poisonous products of bacterial decomposition and fermentation which stimulate new protective growth in the periodontal membrane. It is made up of a fibrous capsule containing granulation tissue infiltrated by polymorphonuclear leucocytes, capillaries, small round cells,

* [The roentgenograph reproductions in this article are made in the "negative" form, thus enabling the reader to view the tissues and diseased areas as he is accustomed to see them in original film.—Ed.]

fibroblasts, endothelial and sometimes epithelial cells. Granulomas vary in size from the head of a pin to a hickory nut. There is another type of granuloma that

do not mean to say that all granulomas go on to cystic formation; most of them do not, but in this type we have the formation of the radicular or root-end cyst.

FIG. 2.

A

B

we speak of as an epitheliated granuloma, the sequel of which is a cyst. The epithelial remnants which are normally found in the periodontal membrane have a tendency to proliferate when stimulated by

Fig. 3 is a typical radicular cyst in which the floor of the nose has been perforated. Cysts have also been known to fill the entire antrum. In this case the cyst undoubtedly originated from the right lateral incisor, which shows an incomplete root-canal filling.

FIG. 3.

FIG. 4.

chronic inflammation, and grow over the inside of the granuloma. Epithelium, being a secretory membrane, secretes a fluid, and the cyst increases in size by pressure at the expense of the bone. I

The X-ray reading of a cyst shows a large dark area with a definite border, but from a roentgenogram one cannot differentiate between a large abscess area and a cyst; one must have the clinical findings. However, the operation is the same. In a large abscess there is always more or less necrotic tissue, which must

be removed surgically. The epithelial lining of the cyst must be entirely curetted out or there will be a recurrence.

shoulder. Three months after the cyst was curetted the patient had improved ninety per cent.

FIG. 5.

A

B

C

D

Fig. 4 is a cyst in the mandible, where the offending tooth has been removed. Five years ago the first molar was ex-

Fig. 5 is a number of roentgenograms of chronic alveolar abscesses. I mean by that, abscesses discharging pus through

FIG. 6.

A

B

tracted because it was giving the patient some trouble, and a bridge was inserted. This was a severe case of neuritis of the

fistulae: A had been discharging pus for three weeks; B had been discharging pus for one year; C had been dis-

charging pus through the cheek for six years. Upon the extraction of this tooth two small pieces of broaches shown by the roentgenogram were found at the apical region; D is a case which had been discharging pus for ten years. From the roentgenogram one cannot tell the duration of the lesion, as all the areas appear to be about the same size. X-ray reading of a chronic alveolar abscess in most cases shows a shading off from the dark area into the light, or surrounding tissues. At the same time one will see cases of typical granuloma readings where pus is discharging. In these cases the fibrous capsule has broken down either by lowered resistance, fatty degeneration, or reinfection through the root-canal. A granuloma may be likened to a bomb with a fuse—we do not always know whether or not it is burning.

Fig. 6 (A, B) shows cases of blind abscesses. For experimental purposes these teeth were opened; pus was found in the canals. These films show about the same reading as chronic abscesses, except that

canal above the pin. In making a diagnosis from a roentgenogram we cannot differentiate between a blind abscess and a chronic abscess, and in some cases be-

FIG. 7.

tween a chronic abscess and a granuloma. One must depend on the clinical diagnosis, as the roentgenogram only shows us the extent of the lesion with which we have to deal.

FIG. 8.

A

B

there is no protecting membrane between the pus and the blood stream, and the toxins are very readily taken up. I believe I am safe in saying that 95 per cent. of the cases where post-crown teeth have been used show no attempt to fill the

Fig. 7 shows a necrotic area. Notice its honeycomb appearance. At the same time absorption of the root is taking place. Where you find the root-apex absorbing, all the drugs at our command will not cure the lesion; surgical means

must be employed, such as root amputation or extraction.

Fig. 8 (A) is a different type of necrosis, *i.e.* syphilis. This case showed a Wassermann 4 plus. It is impossible to differentiate between syphilitic, arsenical,

- (A) Plain paraffin (does not show).

- (C) Paraffin plus bismuth paste plus the gutta-percha point.
- (D) Oxpara.
- (E) Oxpara plus the point.

FIG. 9.

phosphoric, or tubercular necrosis; one must depend on the history of the case, the clinical diagnosis and the blood test. At B is shown the removed sequestrum, which involved the anterior border of the antrum and the floor of the nose on the right side.

Fig. 9 shows the radiability of the different root-canal fillings:

- (F) Chloro-percha.
- (G) Chloro-percha, plus the gutta-percha point.
- (H) Euca-percha.
- (I) Euca-percha plus the point.
- (K) Gutta-percha point only.
- (L) Oxychlorid.

They all show highly radiolucent, with the exception of plain paraffin.

Minimum Requirements for Class "A" Dental Schools

ADOPTED BY

The Dental Educational Council of America

AT LOUISVILLE, KENTUCKY, JULY 24, 1916, AND REVISED AT NEW YORK CITY,
OCTOBER 22, 1917, AND MARCH 26, 1918.

By HENRY L. BANZHAF, B.S., D.D.S., Milwaukee, Wis.,

SECRETARY OF THE COUNCIL.

ALBERT L. MIDGLEY, *President*, Providence, R. I.

J. V. CONZETT, *Vice-president*, Dubuque, Iowa.

HENRY L. BANZHAF, *Secretary-treasurer*, Milwaukee, Wis.

JOHN H. BALDWIN, Louisville, Ky.

L. L. BARBER, Toledo, Ohio.

THOMAS J. BARRETT, Worcester, Mass.

H. E. FRIESELL, Pittsburgh, Pa.

S. W. FOSTER, Atlanta, Ga.

LOUIS MEISBURGER, Buffalo, N. Y.

A. R. MELENDY, Knoxville, Tenn.

M. J. MORAN, Deming, N. Mex.

A. H. REYNOLDS, Philadelphia, Pa.

B. HOLLY SMITH, Baltimore, Md.

GEORGE N. WEST, Chicago, Ill.

HERBERT L. WHEELER, New York City.

ADMINISTRATIVE POLICY.

SECTION 1. (a) The administrative policy of the school must be satisfactory to the Dental Educational Council of America. The dean or other executive officer must hold and have authority to carry out fair ideals of dental education.

(b) The value of the building and equipment (grounds excluded) must be equal to at least \$300 for every student enrolled.

(c) The school must have facilities and equipment for at least twenty-five students in each class.

ENTRANCE REQUIREMENTS.

SEC. 2. (a) The requirements for entrance shall consist of graduation from an accredited high school or academy which requires for graduation not less than fifteen units of high-school work obtained in a four-year course beyond the eighth grade of the elementary school. No conditions on the foregoing entrance requirement shall be allowed.

(b) An accredited high school is defined as one which is accredited as a four-year high school by the United States Bureau of Education, or by a university which is a member of the Association of American Universities, or by the State University of the state in which the high school is located.

(c) In the case of an applicant who is not a graduate from a high school or academy, as defined above, the full equivalent of such education in each individual case must be established, and attested to by the highest public educational officer of the state in which is located the dental school which the applicant seeks to enter.

(d) The entrance credentials of each student enrolled must be kept on file, and open to general inspection, until after graduation. Not later than sixty days after the opening of school the dean shall send to the secretary of the Dental Educational Council, and to the secretary of the local State Board of Dental Examiners, a complete list of the students enrolled, together with a sworn statement

that each student is possessed of the entrance qualifications outlined above.

(c) Students with two full years credit from Class "A" medical schools, approved by the American Medical Association, may be admitted to the sophomore class. No other advanced credit in time may be given in any other case than as above specified. No special students shall be accepted unless they are in possession of the entrance requirements specified above.

(f) The foregoing regulations apply to all students, including those from foreign countries, and regardless of where the applicant expects to practice his profession.

COURSE OF STUDY.

SEC. 3. (a) Beginning with the session of 1917-18 the course must be four years in length, each year to consist of thirty-two weeks and six days in each week. No degrees other than Doctor of Dental Surgery, Doctor of Dental Medicine, or Doctor of Dental Science may be given. Dental subjects must be taught throughout the entire four years. Schools that offer a three-year course with one year of college work as a prerequisite shall not be regarded as satisfactory.

(b) The school must offer a course of at least 4400 hours laboratory and didactic instruction.

(c) The minimum hours devoted to each branch shall be as follows:

| | Hrs. |
|-----------------------------------------------------------------|------|
| Operative and clinical dentistry .. | 1300 |
| Prosthetic technics | 384 |
| Crown and bridge technics | 320 |
| Operative technics | 160 |
| Oral hygiene | 32 |
| Dental anatomy | 96 |
| Orthodontia | 96 |
| Oral surgery | 96 |
| Physies, biology, or both | 192 |
| Chemistry (inorganic—organic— physiological—metallurgy) | 320 |
| Technical drawing | 48 |
| Anatomy | 320 |
| Histology | 128 |
| Pathology (general and dental) .. | 128 |
| Materia medica | 64 |
| Bacteriology | 128 |
| Physiology | 128 |

| | Hrs. |
|-----------------------------------------------------------|-------------|
| Dental rhetoric | 96 |
| Physical diagnosis, anesthesia | 32 |
| Radiology | 32 |
| Jurisprudence, dental history, ethics, economics | 32 |
| Additions to above, or other subjects | 268 |
| Total | 4400 |

TEACHING FACILITIES.

SEC. 4. (a) The classes in dentistry must be taught separately from the classes in any of the other departments, if the dental school in question is part of a university.

(b) The patronage of the infirmary clinic must be such as to give each student at least 150 operations in fillings (gold, inlay, amalgam, cement, root-fillings, etc.), prosthetic work, and orthodontia. Treatments preparatory to the above, and cases of exodontia, must not be included in the number stated above.

(c) In the anatomical laboratory not more than eight students, working in pairs, may be assigned to one cadaver for a complete dissection.

(d) Every twenty students working in the infirmary at any given time must have the undivided services of at least one demonstrator.

(e) Every thirty students working in the scientific laboratories must have the undivided services of at least one instructor.

(f) Every forty students working in the technic laboratories must have the undivided services of at least one instructor.

(g) No persons except those holding the D.D.S., M.D., or bachelors' degree or equivalent, or who hold a license to practice dentistry, shall be employed as instructors.

LABORATORIES AND OTHER FACILITIES.

SEC. 5. (a) The school must be possessed of the following number of laboratories and class rooms, equipped in the following manner:

(b) One chemical laboratory equipped to adequately teach qualitative, quantita-

tive, general inorganic and organic chemistry, and physiological chemistry.

(c) One microscopical laboratory equipped with sufficient high power microscopes so that each student may be possessed of the use of a microscope when he is working in the laboratory.

(d) Sufficient classrooms—at least one of which must be equipped with a lantern for projection.

(e) Sufficient technic laboratories, so that each student in attendance is provided with an individual place for laboratory work.

(f) A dental infirmary, equipped with a sufficient number of dental chairs to adequately serve the senior class. An efficient equipment for sterilizing students' instruments must be provided.

(g) An X-ray outfit for use in conjunction with the dental infirmary.

(h) A dental library constantly available to the students, which shall have at least twice the number of volumes as there are students enrolled in the school.

STATE BOARD RECORD.

SEC. 6. The school must not have more than 25 per cent. failures before the various state boards more than two years in succession.

ATTENDANCE.

SEC. 7. The record of attendance required of students must not be less than 85 per cent. for each year.

PROMOTION OF STUDENTS.

SEC. 8. (a) A student who has incomplete course conditions, or failures, in 60 per cent. of his course for any semester shall be dropped.

(b) A student may not be promoted if he has incomplete conditions or failures in more than 20 per cent. of the course of any year.

(c) A student who fails to remove a condition or failure within twelve months from the time it was incurred shall automatically be dropped from the school.

(d) An incomplete course is one that

has not been completed because of illness or other personal emergency.

PASSING MARK, CONDITIONS AND FAILURES.

SEC. 9. (a) The passing mark shall be 75 per cent.

(b) A grade between 60 and 74 per cent. is defined as a condition.

(c) A grade below 60 per cent. is defined as a failure.

(d) A condition may be removed by examination.

(e) A failure may not be removed except by repetition of the course in part or entirely, *i.e.* by additional work under instruction approved by the dean or the professor in charge of the subject.

(f) A condition which is not removed within thirty days of the opening of the next year automatically becomes a failure, and can then only be removed by a repetition of the course.

(g) If a school grades by letters it shall state (publish) definitely the percentage range value of each letter used in designation of standings.

CLASS "B" DENTAL SCHOOL DEFINED.

Schools which in certain particulars do not meet the requirements for Class "A," but may become eligible for Class "A" without complete reorganization.

CLASS "C" DENTAL SCHOOL DEFINED.

Schools which could not meet the requirements for Class "A" without very extensive improvements and a complete reorganization. Class "C" schools shall be considered "not well-recognized dental schools."

TRANSFER OF DENTAL STUDENTS.

Students of dental schools which have been well recognized, but have lost this recognition, may transfer to well-recognized dental schools, if acceptable to these schools. Such students may be accepted, as far as entrance requirements are concerned, on the requirements of the school in which the student began the study of dentistry.

The Dental Clinic in the National Army Cantonment.

By MALCOLM W. BAYLEY, Louisville, Ky.

THE first dental clinic set up and placed in operation at any military cantonment in the United States—that at Camp Zachary Taylor, Louisville, Ky., under Major Wm. Mann, D.C., dental surgeon in charge—expects to finish very near the top in the efficiency record competitive test inaugurated by the Council of the Association of Military Dental Surgeons, which was held from January 1st to March 31st. If this clinic does attain a high rank, it will undoubtedly be due to the system put into effect by Major Mann last November, the efficiency of which has been so apparent that a second clinic of the same type was opened about the first of March, while work was begun on a building for housing and operating-rooms for fifteen dental surgeons and enlisted men.

Major Mann's report to the War department for the month of December showed that 4929 operations were performed in the entire camp. The salary of the fifty-one dental surgeons then in camp for one month was \$8500, which sum, divided by 4929, made the average cost of each operation \$1.72 for the month.

At the same time, in the clinic, where eleven dental surgeons were employed, there were performed an average of 98 operations per day, or 2450, allowing twenty-five working days per month. The salary of the eleven dental surgeons in the clinic was \$1833.37 for the month, which sum divided by the number of operations showed each to have cost the Government but 74 cents. Of course these figures of expense of operations do not include the cost of equipment or material. The difference in cost between the old and new methods was 98 cents.

Major Mann therefore said in his report: "It is evident from this comparison that under the present system the Government is losing at least half of the services of the commissioned *personnel* of the dental corps, which undoubtedly reflects on the administrative ability of the dental surgeon in charge. I therefore urge that this condition be remedied as quickly as possible."

The new clinics and buildings were the answer.

Unit No. 1, Camp Zachary Taylor, was keeping an accurate record of all the requirements demanded by the Association of Military Dental Surgeons' "efficiency test" before that competition was announced. Strict account is kept of the total hours on duty, the total days' leave, and total holidays. Account is taken of the number of amalgam fillings, cement fillings, extractions (roots and teeth), scalings, root-fillings, abscesses treated, putrescent roots treated, exposed or aching pulps treated, temporary fillings, gutta-percha or cement; and in addition the operations performed are classified, and records are kept of military conduct, neatness both of person and office, and as to how instruments are sterilized and property accounted for.

Each patient at unit No. 1 has a register slip which contains the patient's full name, rank, company, regiment or other organization, age, race, nativity, years of service, disease or injury, with location, complications, sequelæ, etc.; dates and nature of treatments and operations, results and remarks, and the name of the dental surgeon in attendance. The record from these register slips is transferred daily to the operator's daily record. A monthly report also is kept of each

operator, the figures being always at hand and up to date for the dental surgeon's service record.

The unit No. 1 clinic at first treated about 6000 men, increasing this to 10,000 when the organizations were filled. The organizations assigned to this clinic were the 334th and 335th Infantry, all trains—sanitary, supply, ammunition, military police, and headquarters—and 309th Engineers, headquarters troop, and signal corps. Attached to the first clinic were Lieut. Roy D. Gabbert, assistant in charge, and the following 1st lieuts.: Wm. H. Hatcher, B. B. Lowdenback, J. L. Rahm, H. R. Ludwig, Lee V. Sexton, Julius A. Altman, Wm. J. Barto, Joseph W. Golding, Howard Bock, and Louis M. Nelson.

The record of this staff for January 1918 was as follows:

| | No. |
|-----------------------------------|------|
| Amalgam fillings | 2860 |
| Amalgam oxyphosphate fillings ... | 611 |
| Oxyphosphate fillings | 3231 |
| Root-canals filled | 276 |
| Synthetic fillings | 178 |
| Teeth extracted | 1221 |
| Treatments | 1278 |
| Calculus removed | 1455 |
| Pulps devitalized | 94 |
| Pulps extirpated | 173 |
| Prophylaxes | 892 |
| Dental caries | 3938 |
| Sittings | 4355 |
| Patients | 2616 |
| Total operations | 9554 |

Crown and bridge-work operations, 73

The high mark was reached on January 24th, when 193 operations were performed by the eleven men in one day.

The Government is in no way niggardly with regard to the equipment of dental surgeons, the dental equipment at Camp Zachary Taylor being better than a great many civilian dental surgeons enjoy. An interesting description of the property at the first military dental clinic is given herewith by Lieut. Chester Denham, D.C., formerly of Cincinnati, Ohio. He says:

In times of peace, when a dental surgeon is assigned to active duty he usually finds

his portable dental outfit awaiting him: if not awaiting him, it usually shows up at a very early date. Nearly all of the equipment furnished at such time was a portable or field outfit.

The reason the portable or field outfits were furnished in time of peace was because the dental surgeons were constantly being moved about from one post to another. As some of these posts would have only 100 or 200 men, and there being only one dental surgeon to every 1000 men, as allowed by law, it was impossible to have a dental surgeon stationed at every post. With this portable outfit it was comparatively easy for him to tear down and box up, so to speak, as compared to what he would have to do in moving a stationary or heavy equipment.

After war was declared we found that we had not sufficient equipment on hand to supply the needs of the large number of dental surgeons who had been called into the service: so the War department prepared a requisition which covered not only the portable outfits for field service, but stationary outfits for all the National Army and National Guard cantonments. The requisition was made on the basis of giving each cantonment its quota of dental surgeons sufficient to take care of the men stationed at each cantonment at any one time.

It was easy enough to make a list of the articles that we needed, but it was a different story when it came to getting the equipment. It was up to the Medical supply depot, New York, to let the contracts to various dental manufacturers, who in turn have been exhausting every available resource to fill them.

We have at present two dental units equipped and in operation, and the other two will be equipped as soon as the building is erected. [This has since been done.—Ed.] Each unit uses two electric dental engines, with folding wall attachments; ten chairs, ten fountain cuspidor and stand combinations, nine compressed-steel white aseptic cabinets, two electric sterilizers, one small and one large, these made so as to prevent them from burning out. There is one complete equipment for the exodontist for every unit, also a complete laboratory outfit for each unit, and a compressed-air equipment with connections through an electric switch-board to every chair and to the laboratory. There is an atomizer, hot-air syringe, and chip-blower connected with the compressed-air equipment attached to each chair.

We have in the way of instruments, Black's cutting instruments or excavators, Woodson's amalgam pluggers and the Cleve-Dent's plastic

pluggers, S. S. White's forceps and elevators, and Ivory's clamps; in fact, all of our equipment is made by the leading manufacturers of the United States. Our supplies are of the same high standard as our instruments, namely, cements, oxyphosphate, S. S. White; oxyphosphate of copper, black, Ames'; alloy, Caulk's Twentieth Century and S. S. White's True Dentalloy; Caulk's copper amalgam, and others too numerous to mention, of the same high standard.

We have been limited to the equipment and supplies of the "dental supply" table of the Medical Manual in making out our requisitions. There are some few things that we have been unable to get by requisition in the past, because they were not on the supply table, but this is now being revised, and we are endeavoring to have placed on this table such equipment as a nitrous oxid outfit, together with some bone-curets, Winter's chisels, Lecluse elevators, and other equipment and supplies that we find we may need in the future. And I am sure that we shall succeed, as the Government has been very liberal to us in the last few months relative to dental equipment, and I dare say will be just as liberal in the future.

In this connection it may be recalled that in the early days of the camp the Jefferson County Dental Association at Louisville came to the rescue of their brethren there by donating various instruments and burs for the use of the military dental surgeons before certain supplies had arrived. They also offered to do any soldier's work at half price, and invited the military men to bring to them any puzzling cases in which they might be able to render aid.

Major Mann, the dental surgeon in charge, is a great believer in amalgam as a tooth-saver and to make correct restorations. He insists that either amalgam or synthetic porcelain will outlast a gold inlay.

Lieut. Neil J. McCollum, D.C., of West Frankfort, Ill., says, in describing amalgam restorations, that until recently amalgam was the only permanent filling material on the "dental supply" table, but that recently there has been received some DeTrey's synthetic porcelain. Other materials, such as gold, porcelain crowns, and plate teeth are expected. Lieut. McCollum says:

Of all the permanent filling materials now on the market none has yet been found which is superior to amalgam. Where indicated and properly inserted, it is the restoration *par excellence*. When the dental surgeon, whether in the army or civil practice, does more and better amalgam work, more teeth will be saved. A smaller number of teeth will then have to be treated, for it is a fact that many pulpless teeth are not saved teeth. The slogan of the army dental surgeon should be to *SAVE* teeth.

All teeth with chronic infections are removed by us, for two reasons—first to remove the foci of infection, and second to save time. If the dental surgeon attempted to treat all these teeth it would require on an average four or five sittings, and according to statistics at least six teeth could be saved by the use of amalgam in the length of time required for the treatment of one tooth.

The present law provides one dental surgeon for every 1000 enlisted men, and I believe that the National army recruits will require, on an average, four fillings each. Practically every man requires oral prophylaxis. Then an army dental surgeon, in order to give the proper attention to each and every man under his command, would have to complete about thirteen fillings per day on an average, counting 300 working days in the year, to finish his work in this time. This is, of course, exclusive of any treatments or extractions that might be necessary, as well as work done for officers and for members of their families.

In preparing cavities for amalgam restorations, Black's eight rules of cavity preparation are carried out in every instance where practicable. We believe in the separation of all teeth before the filling material is inserted in approximo-occlusal cavities. In order to accomplish this at one sitting we use a very thin steel matrix in an Ivory or Detroit matrix retainer. By the use of a small wooden wedge at the gingival border, sufficient separation is made to give perfect contact when the matrix is removed.

The alloy is thoroughly amalgamated, with as little excess of mercury as possible. The filling is packed by the use of flat-faced instruments, both serrated and smooth. The use of a burnisher is prohibited on a newly inserted filling, as this will cause the mercury to come to the surface, which after a short time will become porous, thereby lessening the edge strength and affording lodgment for food particles. All fillings are carved to conform to the natural outline of the tooth as nearly as practicable, being careful always to restore marginal ridges, cusps, sulci, grooves,

etc. This is done by the use of sharp instruments, always carving from the enamel toward the filling.

As dentists all know, amalgam has always been unjustly abused by the majority of operators, and is looked upon by the laity as a cheap filling material, but I believe almost everyone will agree with me when I say that if the same length of time were spent upon an amalgam restoration as upon a gold inlay or gold filling, it would be superior to either.

Our amalgam restorations are all polished at subsequent sittings, unless it be the last filling for that patient, and in this case some time is allowed for crystallization, when the filling is polished, to avoid the necessity of the patient's returning for this one operation.

Lieut. John O. Lessig of Philadelphia, one of the dental reserve corps men at Camp Zachary Taylor, in speaking of the dental work done in the army, says:

We aim first to prevent dental lesions by prophylaxis, and the saving of teeth where practicable, rather than the restoration of missing ones. Here let me commend the civilian dental surgeons for the wonderful assistance they have rendered and are rendering the army by putting into shape the teeth of many of the new soldiers—especially the Preparedness League of American dentists. The President of the United States has said that every utility should be conserved and used in this great war. Dentistry is certainly a utility of the highest order. Dental sur-

geons have already rendered a valuable service in performing 136,000 free dental operations, furnishing the material free, for men now in the service.

More than 40,000 dental surgeons in this great country are rendering service, and what a wonderful service when we think back to July 1917, when we found that the 67th Regiment, New York National Guard, was the only organization of soldiers whose teeth had been put in perfect condition, ready for transportation across the Atlantic!

Dental treatment should be the same in the army as in private practice—careful and proper treatment no matter what the operation is. It should be given our most conscientious attention, and we should execute the work with the utmost care and skill we possess.

Let me say a word of commendation for those who have come into the Army Dental Corps. It is, indeed, a far-sighted and patriotic act on the part of a dentist to become an officer in the dental corps, for by so doing he has increased his measure of usefulness at the time when his country most needs him. At this time, if he be a true man, a virile man, he desires to be of the utmost service to his country. Many measure their success in the profession in dollars and cents, and I dispute not that every man should have a fair return for his labor. Be that as it may, true success, in or out of the army, lies in the cure effected, the relief given, and the restorations made in the oral cavity where caries of the teeth and other diseases have wrought great destruction.

CORRESPONDENCE

“Radiolucency of Chloro-percha.”

TO THE EDITOR OF THE DENTAL COSMOS:

Sir,—I have just read in the May issue of the DENTAL COSMOS, and also in the April issue of the *Dental Review*, a communication by Dr. W. Clyde Davis relative to the reliability of the X-ray in the diagnosis of roots filled with the old-fashioned chloro-percha in use for the past twenty years. It contained statements which I confess were a surprise to me, and which prompted me to start

The radiograph was taken after the root had been filled for a couple of days and the chloro-percha had been allowed to dry.

The cuspid (Fig. 2) is one in which the root-filling consists of a mixture of the old-fashioned chloro-percha (rather thinner than usually employed) and the ordinary cement powder, and mixed to a thin pasty consistence, in which condition it is as easily worked into the

FIG 1.

FIG. 2.

my “machine” to see whether or not I had been misled by it for the past five years or more.

Accordingly I took a couple of extracted teeth, and without any particular preparation, except to see that I could carry a broach through the apex, I “pumped” my old-fashioned chloro-percha through the canal until it came out in the shape of a little ball on the end of the root. I am sending a radiograph (Fig. 1), and you can judge for yourself whether or not chloro-percha will show in the radiograph.

canals as though it were simply chloro-percha.

You will notice two places where the air was caught in the canal, due to the fact that I was in somewhat of a hurry, but the film clearly shows the filling, and by the way, there are no canal points in any of these fillings.

It seems unfortunate that statements of this character should be published so widely as this has been without first getting conclusive proof. Might there not be something wrong with the author’s machine, or perhaps with his method of

developing? If I am wrong, I should be glad to know it, but I think I can see a filling in the roots, extending through the apex of the root, and collected in a little ball on the end of the root.

If this experiment is of any value you

have my permission to use it as you wish.

Yours for better root-work,

N. A. DEWITT, D.M.D.

CAMBRIDGE, MASS., June 6, 1918.

Scurvy-like Pyorrhea at "the Front."

TO THE EDITOR OF THE DENTAL COSMOS:

Sir,—I have had occasion in my practice to see among the American soldiers here quite a large number of cases of pyorrhea alveolaris. The cases were of such a grave nature that they resembled more nearly scurvy than simple pyorrhea. I found the mouths of these men to be in very bad condition from the hygienic standpoint alone, so bad that it was sufficient cause to account for the gum conditions which I found. I know that in the United States there is an important movement for dental prophylaxis, and trust that by publishing this letter in the DENTAL COSMOS you will convey to the profession the necessity of at once sending to France a dozen prophylaxis nurses who could devote themselves to caring for our men here, who are very sadly in need of their services in very many cases. Surely this is a very small service to ask for our men, who stand so sorely in need of it.

Yours very sincerely,

D. S. KRITCHEVSKI.

PARIS, FRANCE, May 25, 1918.

A Case of Ptosis as the Result of Pulpitis.

TO THE EDITOR OF THE DENTAL COSMOS:

Sir,—I would like to report a case that came under my observation while I was stationed at Camp Gordon, Ga.

A ptosis of the left upper eyelid, the onset of which was coincident with an acute attack of neuralgia, was traced to a pulpitis in the left upper second bicuspids.

The disappearance of the neuralgia

was followed very closely by an abatement of the ptosis with a complete return to normal in less than a week.

None of those in charge of the eye and ear clinic had seen a similar case.

Respectfully,

HENRY P. WADSWORTH,
M.D., D.D.S., Lt.D.R.C.

CAMP MERRITT, N. J., July 8, 1918.

PROCEEDINGS OF SOCIETIES

Academy of Stomatology of Philadelphia.

Monthly Meeting, Thursday Evening, May 16, 1918.

THE meeting was called to order by the president, Dr. Jaquette, at 8.15 P.M.

The minutes of the last meeting and the report of the Council were read by the secretary and approved.

The Secretary read communications from the following, thanking the society for electing them to honorary membership: Dr. J. D. Thomas, Dr. H. C. Register, Dr. E. C. Kirk, and Dr. Thos. C. Stellwagen through his son. These letters were placed on file.

The President then called on Dr. L. A. FAUGHT to read his paper, entitled "Non-cohesive Gold."

[This paper is printed in full at page 685 of the present issue of the COSMOS.]

Dr. OTTO E. INGLIS then read a paper entitled "A Comparison of Office Policies, with Special Reference to Pulp Exposure or Death."

[This paper is printed in full at page 692 of the present issue of the COSMOS.]

DISCUSSIONS OF PAPERS BY DRS. FAUGHT AND INGLIS.

Dr. H. C. Register. Dr. Faught has given us a most interesting paper on a very old subject, one that appeals to me, however, as being always new, because it continues to mean so much to both the operator and the patient. From clinical observation there is reason to believe that the results obtained from non-cohesive gold fillings are absolutely dependable, providing the cavities are formed along anatomical lines.

I have seen many fillings of the operators of long ago doing continued service for upward of three-quarters of a century; and I have a few of my own made by this method, still "holding the fort" after forty-odd years of service. I shall endeavor to show how non-cohesive gold foil in the form of cylinders and tape saves teeth, and why it appeals to me as being the one universal method to use where gold is indicated.

Gold does not undergo any physical or chemical change in the mouth; it is compatible with living structure, and when used in non-cohesive form for filling teeth its thermal conductivity is lessened and the vital dentin is stimulated to throw out a plasma, which seals the tubules, and this in turn also acts as a non-conductor; also, packing the gold in this form saves time in the construction of the filling, and protects the margins against mechanical injury while filling.

Of course the laws leading up to such a consummation must be observed. We meet with many cases of natural secondary dentin protection in cases of accidental exposure or mechanical attrition where the conditions are favorable. I recall a case where the entire enamel of the labial surface of the upper left central incisor and a part of the lateral were destroyed by the chemical action of a "sour drop" remaining on these surfaces over night. The patient pushed the acid candy there with his tongue, and went to sleep. This was practically a case of acute erosion. The merging of the enamel endings into the

dentin clearly defined the two kinds of structure, and brought to view the striated appearance of the dentin as viewed through a strong magnifying glass, presenting the most beautiful living specimen of these tissues I ever saw. I watched the formation of secondary dentin change a most sensitive surface into one that was horn-like and insensitive.

Gold fillings, cohesive from start to finish, are in my judgment unreliable for very long service, on account of the injury to the tooth, especially the dentin, in placing the filling.

Porcelain and pure gold inlays may add longevity to carious teeth when a long-service insoluble cement is found, for the cement in this class of work is the material that saves the tooth. Gutta-percha is quite limited in its application but a most compatible material, while the cements are all temporary.

Probably seventy-five per cent. of the teeth filled are filled with amalgam. Of this total probably twenty-five per cent. give a service of ten years. Ten years is not a long service, yet it proves that alloy fillings will save teeth aided by the protection of this same deposit of plasma by the dentin fibrils. When we get a perfectly balanced, chemically combined amalgam that is unchangeable, we shall have still better results.

So we are left the one method as demonstrated in actual service for making fillings which will last three-quarters of a century or more, namely, soft or non-cohesive gold in the form of cylinders and tape as described by Dr. Faught. I think Dr. Faught is in error regarding Abbey's non-cohesive gold foil remaining non-cohesive under all conditions. Dr. George Ellis demonstrated to me many years before his death that by annealing each leaf separately on both sides to a cherry red the surface treatment given the foil in its manufacture was burned off, and the foil regained its cohesiveness.

Dr. Inglis' paper fits into Dr. Faught's, the two forming an interesting symposium upon early treatment.

He calls attention to the importance of early discovery of cavities, and their immediate filling, even to pinhead cavities. This in my judgment is wise treat-

ment, and non-cohesive gold in the form of cylinders and tape is the best material for such restorations.

Dr. Inglis also calls attention to the use of the electric mouth lamp in locating approximal cavities. The use of the electric mouth lamp has given me much satisfaction in this class of examinations. By using a black muslin cover thrown over the heads of patient and operator, thereby excluding the light—practically a dark-room—the electric lamp, exposed on one side only by using a guard, illuminates the teeth so perfectly that any carious spot present in the incising teeth—from cuspid to cuspid—is immediately brought to view.

In large breaks in bicuspid and molars some experience is required to note the absence of the natural translucency, but the discolored border and knuckling contact show up immediately.

Many cavities thus found are very extensive, and yet are passed over without detection by the ordinary examination with an exploring needle. Many approximal cavities thus discovered necessitate cutting through the occlusal wall, thereby forming a compound cavity. I will briefly outline my method of restoring a complicated cavity with non-cohesive and cohesive gold combined. The cavity is formed with a flat base at the cervical wall. Do not undercut near enamel, for enamel thus treated is limitedly devitalized—and this, in my judgment, is largely the cause of so many failures of fillings at the cervical margin.

The buccal and palatine cavity walls are slightly beveled outwardly, thereby retaining the enamel rods in normal strength from periphery to dento-enamel junction. The cavity in the occlusal wall is terminated in a dovetail anchorage spreading laterally, with straight walls extending through the whole depth of the enamel to the occlusal step, and at times slightly grooved in the dentin.

Extensive molar contours may receive two grooves, one on each side of the cavity from tuberosity to dentin in alignment with enamel rods, made with a fissure bur to half its width. A planished copper matrix, sufficiently wide to include the cavity from the cervical wall to

just within the contact point with adjoining tooth, is ligated to the tooth and burnished from the inside to contour form against the adjoining tooth. If the dentin is sensitive or the pulpal wall thin, the dentin is given a coating of para-chloro-percha. This immediately relieves all irritation of the exposed dentin, and obviates thermal shock. The cylinders are laid on the cervical wall with one end in contact with the pulpal wall, and the other end against the matrix.

The cylinders are placed with special pliers in regular order, and packed under a pellet of bibulous paper with special pliers and hand pressure, and later with a plugger in the mechanical mallet, until the cavity is filled even with the occlusal step. This is quickly done; then several pieces, as required, of mat gold unannealed are packed over the entire gold floor and into the occlusal dovetail, this being followed by several layers as required of annealed cohesive mat gold, carefully packed by hand and mallet force. Rolled cohesive gold from No. 30 or 60 up to 120, cut in size to easily lie in the cavity, is now used.

The gold is laid in laminae from the locking dovetail to the adjoining tooth, and packed as tightly as possible. This slightly wedges the teeth apart as the packing is done, and sufficient space is gained to allow a Gordon White saw to pass through the excess, permitting complete finishing, and return of the tooth to its knuckling contact. This latter part of the work is most advantageously done a few days later, as the teeth having responded to the wedging process do not constantly spring together during the finishing. The death of the pulp seems likely to spell the doom of a tooth, first, because of the tooth's physical inefficiency to maintain itself—and consequently disintegration, aside from caries, takes place; and second, the septic foci formed by decomposition of the organic matter, which includes the pulp and one-third the dentin, are in the light of recent investigations likely to force extraction in spite of apparent comfort.

Devitalization and disintegration are synonymous terms as applied to devital-

ized teeth, and until original research points a way to safe treatment of root-canals, we must bend our effort toward pulp conservation.

Dr. Inglis. In approximal cavities in incisors I occasionally use a combination of non-cohesive and cohesive gold. The gold is used in ropes or tape packed so as to fill an entire angle from the pulpal wall out, each mass being thoroughly condensed. Successive masses so packed finally leave an accessible unfilled concavity into which cohesive gold is placed, as a key to complete the filling. This is much easier than to attempt to turn in non-cohesive gold with the small pyramidal plugger used for that purpose.

Dr. S. B. Luckie. I have not had as much experience with non-cohesive gold foil as my friend Dr. Faught has, although we probably entered practice at about the same time. I did for many years, however, at the suggestion of Dr. Bonwill, use Abbey's foil, both the non-cohesive and the cohesive. In seeing Dr. Bonwill operate, I learned that he could put in contour fillings with Abbey's non-cohesive foil. I attempted it, and feel that I succeeded very well; but my principal success has been with the two kinds of gold, the non-cohesive in the cervical portion of the cavity, and the cohesive for the buccal and labial walls and the remaining portion of the cavity, somewhat as described by Dr. Inglis. In the use of non-cohesive gold foil, there is no doubt that it is more compatible with the dentin than cohesive gold, which is more stubborn, and requires more force to adapt it to the walls of the cavity. By lining the cavity with the non-cohesive gold, as brought out by Dr. Register, the dentin has an opportunity to heal.

In regard to Dr. Inglis' paper, I think the whole gist of it brings us right back to the fact that we must practice prophylaxis. We must not only practice it, but teach the importance of it. As for educating the public, as suggested by the essayist, I do not think the method proposed would be a successful one. It appears to me that if the laity will not listen to the words of the family dentist they would hardly be influenced by what they might read in the public press. It

is a method that has never been tried, and no doubt it is worthy of a trial. I think it would be well if the society would take it up, in a systematic manner, as suggested in the paper, with the hope that it would result in educating the mass of the people to appreciate prophylaxis.

Dr. R. E. Denney. Dr. Luckie spoke rather disparagingly of the plan of spreading information among the public by means of pamphlets. My brother and I have a common waiting-room. He is an oculist, and has pamphlets containing certain information about the eye on the table in the waiting-room, and I find that nearly all of my patients come into my office with one of these pamphlets in their hands. I find that people are very keen about getting any information they can concerning themselves, and I believe the plan Dr. Inglis suggests is a very good one. I think we are all too much afraid of doing something that would be considered unethical, and are inclined to let the newspapers and magazines do the educational work that we should do.

Dr. F. D. Gardiner. I never could see much use in discussing which kind of gold is the best to preserve teeth. The kind of gold used should depend entirely upon the skill and preference of the operator. If he is more skilful in the use of non-cohesive gold than he is in the use of the cohesive, he will succeed best with the non-cohesive, and *vice versa*. He should be equally skilled in the use of both. In that case he can use both forms, either singly or combined. He ought to be able to avail himself of the advantages of all forms of gold.

I have had rather an extensive experience with the use of non-cohesive gold entirely in the same operation. I have also used it in combination with cohesive gold, and I have used cohesive gold exclusively. I could do just as good work with one form as with the other. I have used the crystalline form, and equally good results can be obtained with that. It makes no difference whether cohesive gold can be made "soft" or not, if it is soft when you use it. Any cohesive gold, no matter how cohesive it is, if exposed

to the air and allowed to become stale, will become soft or non-cohesive, and you cannot make it cohere without annealing. One who is going to use gold should become skilled in the use of all forms, because each one has its place. There are many operations that can be performed with cohesive gold that could not be done skilfully with non-cohesive.

With regard to Dr. Inglis' paper, undoubtedly the practice of the future should be that of prevention. My practice has been gradually drifting into preventive treatment for nearly twenty years, and I never obtained as gratifying results before as I have obtained since I adopted the practice of prevention. Disease can be prevented if we are only willing to take the trouble to do it, and are thorough and systematic enough.

Dr. Geo. F. Logan. Dr. Faught said he was going to read a primary paper. As far as soft gold is concerned, my experience is so primary that I do not think I shall discuss it at all. I am glad he mentioned the care we should take to avoid injury to the enamel prisms. Dr. Register emphasized this point. I believe that if we primary gold workers have more success with inlays than we had with the old method, the success is due to the fact that the former method enables us to avoid injuring the margins of the cavity.

Dr. Inglis mentioned educating the public. That is an interesting subject, but I think he begins at the wrong end. It seems to me that the school is the place to educate the public. The teacher speaks with an authority that the newspaper, the magazine, or even the dentist cannot. The child accepts what the teacher says as final. It is an insidious method of impressing upon and implanting into the minds of the children a fact that grows up with them. I think with very little effort we could interest the school boards, and have this work done through the schools. Instead of using textbooks on hygiene that instruct children not to use pins with which to pick the teeth because they scratch the enamel, let us get authority to revise the textbooks, and tell them something about the first molar, etc. I have had mothers

send children to have the first molar extracted. When I sent the child back with the information that it was a second tooth it was met with the positive statement that it was not, and the child was sent back to me. The present textbooks on hygiene say practically nothing about vital dental subjects. I think there is nothing that could be taught through hygiene that is more important than the care of the teeth. Children can help to take care of their teeth. It is all very well to instruct them about the other organs, but they cannot make use of their knowledge to take care of them. They must go to the physician.

Dr. Wallace wrote a small book a few years ago in which he claimed that proper preventive measures would actually prevent caries. The book caused quite a stir in the profession at the time it was published. I think that Dr. Wallace was a little over-enthusiastic, but his suggestion was a long step in the right direction.

Somebody mentioned root-fillings. Dr. Register called attention to the 33½ per cent. of organic matter in dentin. There has been a great deal of discussion as to the possibility of destroying bacteria in the tubuli of the dentin. Some claim that there are no bacteria there. We know that there are tubuli, and that there is pabulum in them. The sodium-potassium method is very effective, but it seems to me that Dr. Howe's method is the better to sterilize the dentin. We can close up the apical foramen and force the silver nitrate and ammonia into the tubuli by pressure—of course, if the shade of the tooth is unimportant because of its position or condition.

Dr. A. Kassab. With regard to Dr. Inglis' paper, I would say that with our present knowledge of the relation of infection of the teeth to systemic diseases, I agree heartily with him about educating the public by articles prepared by the state or the national dental society. During the last month an article was published in one of the magazines entitled "How I Found Health in the Dentist's Chair," and I think that within one week it was mentioned to me by my patients more than half a dozen times. This

shows the people are anxious to get something that will help them in securing good health if they do not have it; or in taking care of it, if they do. The school is the place where children should be taught oral hygiene; but who can teach them? Many teachers are ignorant of the principles of it. In our town, through the efforts of Dr. Luckie, we have secured a set of slides, and a committee has volunteered to spread information in the schools throughout Delaware county. Permission was obtained for the members of this committee to go into the schools before the pupils from the fourth grade up, and speak to them about the importance of oral hygiene. You would be surprised to know how many, not of the children, but of the teachers, would speak to us afterward and say that they had not known these things. If they did not know them, they could not teach them. Until the time comes when the teachers receive instruction in this subject, they cannot teach it; and I agree that any method that can bring before the public the importance of saving the pearls which nature has given them is of value, because I believe that on their health depends, to a great extent, the health of the individual.

Dr. Logan. In answer to the objection of the gentleman who has just spoken, I would say that if this information were embodied in the textbooks and therefore a part of the course, it would be the teachers' business to know about it. It would be an easy matter to revise the textbooks and give the information to the teachers in that way.

Dr. Inglis. The school is the place for the child to learn oral hygiene, but there are millions of people not in the schools who are present or prospective patients. Something should be done to educate these people, and the constant presentation to them of authoritative knowledge through the medium suggested should finally move them into such action as will make prophylaxis possible. As it is, we get the consequences of neglect.

The readers of the papers received a vote of thanks. The meeting adjourned at 9.25 P.M.

BIBLIOGRAPHICAL

ESSENTIALS OF LABORATORY DIAGNOSIS. Designed for Students and Practitioners. By FRANCIS ASHLEY FAUGHT, M.D., Director of the Laboratory of the Department of Clinical Medicine and Assistant to the Professor of Clinical Medicine, Medico-Chirurgical College, etc., Philadelphia, Pa. Sixth Edition, revised. Philadelphia: F. A. Davis Company. 1917.

It is unlikely that this admirable work will find a place in the library of many dentists. It deals with a subject which is distinctly outside the province of dental practice. This does not mean that the study of the pulse, the blood-picture, uranalysis, and many bacteriologic methods are immaterial to an efficient and successful treatment of oral and dental lesions. It means simply that the subject is so complex and so intricate that the dentist cannot afford to train himself to make many of the tests accurately or to interpret the results rationally. He must refer this work, as does the general practitioner, to the specialist.

From a dental standpoint, the book needs enlargement of the section on the chemistry of the saliva, and a special section on the collection of material from oral infectious foci for bacteriologic examination. From the general standpoint, this work is very complete, concise, and clear. The print is large; the size, form, and make-up of the book facilitate convenience of usage, and in particular the table of contents and the index make reference easy and rapid.

GENERAL PATHOLOGY AND BACTERIOLOGY FOR DENTAL STUDENTS. By GUTHRIE MCCONNELL, M.D., Director of the Clinical and Roentgenological Laboratories of the Waterloo Medical Society, Iowa, Capt. M.R.C., U. S. A., formerly Professor of Pathology and Bacteriology in the Philadelphia Dental College and in the Medical Department, Temple University; formerly Demonstrator of Pathology, Medico-Chirurgical College of Philadelphia; formerly Assistant Demonstrator of Histology, University of Pennsylvania, etc. Second Edition, revised. Philadelphia and London: W. B. Saunders Company. 1918.

This little book is designed for two groups: First, practitioners of dentistry who received their training before the modern, fundamentally medical viewpoint was appreciated; second, dental students. For the former group this book may be extremely desirable. A short, concise, simple exposition of pathologic facts and concepts must make this group more valuable in its service to the community.

For the latter group, dental students, the value of this book is questionable. Undoubtedly it will enable them to pass the "state board" examination, but will they have from it as deep, as real, as comprehensive a "pathologic sense" as will that student who has in addition to laboratory work and lectures made collateral reference to the more elaborate texts? The student who is to practice dentistry admittedly needs different

training from that given to him who will practice general medicine, obstetrics, or abdominal surgery—but the point of divergence lies after, not before the instruction in general pathology.

A critique of this book ultimately resolves itself into a consideration of this whole class of books—books which are intermediate between the more complete, scholarly textbooks and the totally inadequate “quiz compend.” If it be admitted that there is a place for such an “intermediate” book, then in this one the treatment of certain subjects, as inflammation, bone diseases, and the streptococci—subjects all of high dental interest—stands out as particularly insufficient.

Books Received.

Books received are acknowledged in this column, and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender. Selections will be made for review in the interests of our readers and as space permits.

“Electrolytic Medication (Ionization)—Theory, Technique, and Clinical Applications.” Published by the Ritter Dental Mfg. Co., Rochester, N. Y., Chicago, Philadelphia, New York. 1918.

“How to Keep Well?” [Polish.] A Popular Textbook on Oral Hygiene, Descriptive and Instructive. By W. NALENCZ-KONIUSZEWSKI, D.D.S. (Published for the benefit of the three million Polish-speaking Americans.) Chicago, Ill.: Polish Peoples Publishing Co. 1917.

“An Investigation of the Methods of Disinfection as Carried Out in Dental Offices.”

By ADÁM ROBERTA HOLMES, B.A., M.A., Research Laboratory, University of California and California State Dental Association. Reprinted from the *Journal of the California State Dental Association* of March and April, 1918. [Pamphlet.]

“Nine Humorous Tales.” By ANTON CHEKHOV. Translated by ISAAC GOLDBERG and HENRY T. SCHNITTKIND. Boston: The Stratford Company. 1918. Price 25 cents.

“Interpretation of Dental and Maxillary Roentgenograms.” By ROBERT H. IVY, M.D., D.D.S., Major Medical Reserve Corps, U. S. Army; Associate Surgeon, Columbia Hospital, Milwaukee; formerly Instructor in Oral Surgery, University of Pennsylvania. With 259 illustrations. St. Louis: C. V. Mosby Company. 1918.

“Qualitative Chemical Analysis.” A Laboratory Manual of Qualitative Chemical Analysis. By A. R. BLISS, Jr., M.D., Ph.G., Professor of Pharmacology, School of Medicine, Emory University, Atlanta, Ga.; formerly Professor of Chemistry and Pharmacology, Graduate School of Medicine, University of Alabama. Second Edition, revised and reset; 194 pages with working tables. Philadelphia and London: W. B. Saunders Company, 1918. Cloth, \$2.25 net.

“Army Dentistry.” Forsyth Lectures for the Army Dental Reserve Corps. By FREDERICK A. KEYES, D.M.D., former Visiting Dentist, St. Vincent’s Orphanage, Boston; Consulting Dentist, State Hospital, Medfield, Mass.; Librarian and Curator of the Museum, Forsyth Dental Infirmary, Boston. New York and London: D. Appleton & Co. 1918.

REVIEW OF CURRENT DENTAL LITERATURE

[*Lancet*, London, April 20, 1918.]

The Modern English Skull. BY F. G. PARSONS.

The dentist in general and the orthodontist in particular realize the correlation between the teeth and the facial contours and profiles. Perhaps it is not yet fully appreciated that the definition of the norm is an indispensable prerequisite to the study of such correlation, or that this definition has by no means been yet accepted by the anthropologist. The problem in England is infinitely simple compared with the problem in this country, whose basic complexity has for so long a time been signalized by Boas.

Parsons introduces his considerations with the comment that it is a curious thing that one of the skull forms of which we know the least is that of the modern Englishman. The reason, of course, is that we so seldom have the opportunity of studying it, since all the skulls in our dissecting rooms are cut to pieces, while those which we use in the lectures are collected from various parts of Europe. There are, however, in London a few skulls the identity of which is known, and one or the other of these is often used as the type of an English skull, though not always the same one. Parsons proposes to make a short study of these skulls with the view of determining whether they may all be regarded justly as typically English.

After a very technical anthropometric survey he accepts the prosaic and likely fact that the modern Londoner differs wonderfully little in his head form from his Saxon ancestor, except that he has lost 2 or 3 mm. in his skull length. In England, as in Norway, the brachycephalic, Alpine, or Slav blood has not had the chance of superseding and stamping out the Nordic, which it has done, if German prisoners are any test, throughout the greater part of Germany.

The Treatment of Hemophilia. BY LOUIS T. DE M. SAJOUS.

Hemophilia is one of the big, ingrained fears of the dental profession. In the first place it is well to recognize that clinically hemophilia does not correspond with a pathologic entity. It may be due to deficiency in available calcium in the blood; to infection, as *e.g.* in the melena neonatorum: it may occur in hepatic cirrhosis. However, in its strict sense this term may be limited to that constitutional hereditary defect which in general is sex-linked, and which follows a modified form of the Mendelian law. This seems to be characterized by a delay in the coagulation time in the initial step of coagulation, which initial step normally is "a rendering of the platelets available by some process like solution." The platelets, while normal in numbers, seem abnormally resistant, and do not give up their prothrombin readily enough. Hemophilic blood plasma is thus likely to contain only minimal amounts of dissolved prothrombin. From this viewpoint, the rational treatment of hemophilia would consist, under emergency conditions, in supplying at once artificially the lack of prothrombin, and during the intervals between hemorrhages, either in promoting the formation of less resistant platelets or possibly in supplying some agent which would hasten their dissolution.

For convenience this discussion may be divided into seven different headings, each of which is concerned with some form of treatment. These are (1) administration of calcium in one form or another, (2) administration of gelatin, (3) administration of normal blood serum, (4) administration of defibrinated human blood, (5) the transfusion of human blood, (6) the introduction of organic coagulating principle or principles

lacking in the blood of hemophiliacs, and (7) local treatment.

(1) In general, the consensus of opinion today inclines to the view that the administration of calcium chlorid or lactate does not definitely lessen the tendency to hemorrhage. This is accounted for by the now well-known fact that in these cases calcium is nearly always present in normal amount in the blood. However, for a small minority of hemophiliacs this form of treatment is indicated.

(2) A number of years ago it was thought that gelatin exerted a definite effect in arresting obstinate hemophilic bleeding. Where it is to be introduced hypodermically, specially prepared sterile gelatin should be employed. The solution used may be of 1 to 10 per cent. strength, preferably the latter. It has been specified that not less than 2 gm. be given at a dose. On the whole, it must be recognized that systemic use of gelatin is by no means a certain therapeutic measure, though sometimes good results follow, at least temporarily.

(3) Much more efficient than the two above methods has been the use of normal blood serum. In the therapeutic administration of serum the difficulty is met by the injection of ready-formed thrombin—which remains in serum after clotting—and this is seemingly the chief feature of utility in such a procedure. An artificial, extraneous coagulating power is thus conferred on the blood in a manner analogous to the induction of passive immunity by injection of immune serum. Fresh serum from any mammalian species seems to be effectual, though it is advisable that sera from the ox and dog be avoided, as being more likely than others to induce toxic symptoms. The most potent sera have been found in the order of their efficacy to be human, rabbit, and horse sera. The dose of serum given subcutaneously ranges from 10 or 15 mils in a mild case or young infant to 30 or 50 mils in a more severe case or older child. At times one or two doses suffice to control severe hemorrhage. In urgent cases the injection may be repeated at intervals of 4 to 6 hours, while in other instances injections may be appropriately given once daily, or until no new hemorrhages have taken place for 24 hours. Intravenous administration of serum has oc-

asionally been carried out and may of course be expected to yield results even more prompt than those following hypodermic use. The dosage is smaller, viz, 10 to 20 mils in the severe cases. Apparently but little trouble has been experienced from anaphylactic symptoms; although upon the slightest indication of these symptoms the kind of serum used should be at once changed. However, this method of treatment yields more complete results in cases of sporadic or accidental hemophilia than in the cases of true or hereditary hemophilia. In default of fresh serum, regular antitoxin sera, especially diphtheria antitoxin, have been used, often with satisfactory results, whether injected or applied locally.

Injection of serum on the day before an operative procedure in a bleeder has repeatedly yielded successful prophylactic results.

(4) Defibrinated human blood has been substituted by some for serum. From the standpoint of coagulation it is probably but little, if at all, superior to serum alone.

(5) From the standpoint of recorded clinical observations the effects of whole blood transfusion seem to have been slightly superior to those of procedures (3) and (4). On the whole, blood transfusion, in comparison with serum administration, may perhaps be held especially indicated in the more severe cases, though the circumstances attending the individual case might easily outweigh other considerations.

(6) This group includes quite a miscellaneous assortment: raw meat juice, cephalin, a solution asserted to contain the thrombokinetic substance in nearly its pure form in addition to the pro-ferment prothrombin, Witte's peptone, and organ extracts. Among the latter, thyroid medication seems advisable in the entire group of "bleeders." Over serum or blood treatment this measure has obviously the advantage of greater ease of application. Ovarian extract has been advocated for these conditions, although the results on the whole do not seem to have been as favorable as those obtained with thyroid preparations.

(7) Under the heading of local treatment are included a number of distinct ideas. Ordinary hemostatic agents, as ferric solutions, stypticin, antipyrin, etc., together with local pressure, seem useless generally. Calcium chlorid, gelatin, or adrenalin solutions, while

sometimes effectual, cannot be resorted to invariably. Thermocautery has been used successfully as a last resort in a case of bleeding from the gums. The best local methods are, as in the constitutional treatment, those that overcome the specific deficiency in prothrombin or thromboplastic substance, which is responsible for the delay in coagulation at the bleeding point.

Mere kneading of the tissues surrounding the site of hemorrhage has at times proved sufficient to arrest the flow. Such results are accounted for on the assumption of a liberation of an additional amount of thrombokinase from the kneaded tissues, much larger quantities of the kinase being required to induce rapid clotting in hemophilic than in normal blood.

A few drops of the practitioner's own blood or of normal blood from another person will frequently arrest the hemorrhage. Fresh normal blood serum used in a dressing over the point involved, after cleansing the latter, exerts a powerful coagulating influence. For intranasal hemorrhage or bleeding teeth in hemophiliacs, serum is likewise appropriate, applied in the manner usual in these situations.

Fresh goiter tissue material—parenchymatous, hyperplastic thyroid material, not cystic or colloid goiter tissue—has been advanced as the most effectual local hemostatic for hemophilic hemorrhage.

An extract from the fresh liver tissue of rabbit or other animal has been advised as a source of thrombokinase. Extracts of testis, thymus, ovarian tissue, as well as of spleen and lymph nodes, also cephalin, have been used according to various reports with some clinical success.

In all but the mildest cases combined local and systemic measures are advantageous, the former having for their purpose to check the bleeding immediately, while the latter assist in preventing recurrence, and, if necessary, reach sites of hemorrhage inaccessible to direct remedial applications.

[*Journal of the National Dental Association*, June 1918.]

A New Continuous-Gum Set. BY FREDERICK H. NIES.

The continuous-gum set is too artistic a piece of work to pass away, but despite its

obvious beauty, its natural appearance, and its cleanliness, it has been passing. One who is sensitive to the modern trend of dental thought realizes that there is at present a far larger field of usefulness for dentures than there has been for many years. Nies has made a unique improvement in continuous-gum construction, in that he has divided it into two parts instead of one whole. This simplification and standardization of the old method will do much toward encouraging practitioners to adopt a procedure which admittedly is without peer.

The central idea of Nies' modification is that the plate and teeth are separate. An impression is taken by a modification of Greene's method. The muscle-molded impression gives a cast on the die of which it is possible to swage a plate that does not impinge on the muscles or frenum, that causes no discomfort, and that clings firmly to the roof of the mouth. This is highly important in a continuous-gum set, which cannot well be trimmed after the porcelain is fused. The base-plate is made as usual, and from this the bite is adjusted. All-porcelain crowns, fitting over iridio-platinum posts, are then ground to articulate. These crowns sit in platinum cups, which in turn are soldered to the base-plate. Nies draws a seamless cup. The neck of the crown is measured with thin wire. A mandrel is chosen to fit the wire measurement. With the aid of a steel draw-plate a platinum disk is drawn down to a cup fitting the neck of the crown snugly, and corresponding in size to the wire measurement. From an impression of the crown a die is made of Melotte's metal, and the platinum cup swaged over it. This is a tedious process, and at present suitable cups can be secured on the market.

In the discussion L. E. Custer suggests the following substitute method for making the cups: Take a 30-gage dead-annealed platinum wire, wind it around the neck of the tooth three, four, or five times according to the desired depth of the cup. Remove the coil, place it upon a sheet of platinum, and, using a piece of Ames' solder, solidify the platinum coil into a seamless band, at the same time uniting it to the sheet platinum forming the bottom of the cup. Such a cup possesses an advantage in that it presents a corrugated surface on the outside for better attachment

to porcelain, and on the inside for the cement.

Each cup is now placed on its crown, carefully burnished to it, and trimmed. A post-hole is cut, and the post that was originally fitted during the setting up and articulation of the teeth is now forced through into the crown to a suitable depth. The post and platinum cup are firmly waxed together, invested, and soldered with high-fusing platinum solder. When this is done, the posts and cups are fitted upon their corresponding teeth, and the whole is adjusted to correct position on the base-plate with wax. The porcelain crowns are carefully removed, the posts, cups, and plate invested and soldered. The crowns are now reset in the platinum cups and coated just above the cups with oil to prevent adhesion of the porcelain body which, moistened with dextrin, is now applied. The application of the porcelain, its carving and baking, is now done as usual. When this is done, the crowns are cemented in place, preferably with Protosyn or with oxyphosphate or red sulfur.

This method lends itself easily to meet special conditions. For instance, where there has been local or general resorption of the alveolar process, at such areas the platinum cups may be raised as needed above the base-plate by means of varying lengths of iridio-platinum posts. In these cases additional reinforcement should be added. One way is by inserting a strip of 28-gage platinum plate upright between the bottom of the cups and the plate.

The obvious advantages of this method are—(1) It is easier to adjust the teeth, to make corrections and repairs; (2) the strength and translucency of the teeth are not lessened by exposure to the extremely high temperatures of soldering platinum and fusing porcelain; and (3) the volume and weight of the finished denture are less.

[*Schweizerische Vierteljahrsschrift für Zahnheilkunde*, Zurich, 1917. No. 4.]

A Clinical and Bacteriological Study of the Reinfection of Root-canals, especially After Treatment with Tricresol-formalin and Peruvian Balsam-iodoform.

By MARCEL CEVEY.

From many sides this article is admirable. The subject is important and opportune, it has been intelligently analyzed, and the study

of its component problems has been carried out with painstaking industry. In spite of the volume of this research the legitimate conclusions are self-evident. Cevey was induced to take up this work by the many cases which returned unsatisfied after the treatment of pulpal gangrene with tricresol and formalin. This was in reality a phase of the larger problem, a reinvestigation of the view so emphatically presented by Mayrhofer, that our most powerful antiseptics, even after a successful enlargement of the canal with aqua regia, cannot destroy the bacteria harbored within the root-canal.

To secure valid results it was necessary to insure against reinfection of the canal from the saliva with its organisms seeping through the sealing of the dressing. The choice of such an efficient sealing was essential for Cevey's experimental work, but we must not overlook the fact that it can at once be extended into the field of practice. For such a sealing, simply zinc oxid mixed with eugenol suffices. This was suggested by Mayrhofer. This cement must be mixed quite thick, and the zinc oxid must be anhydrous, to insure rapid setting.

In brief, the method of investigation was as follows: The history and present condition of each tooth and of each case was noted. Diagnosis was made from the clinical data. A radiograph was taken, on the basis of which the original diagnosis was reconsidered if necessary. At the next visit a bacteriological examination was begun—a bouillon culture (aerobic), an agar tube (anaerobic), and a smear direct from the canal. The tricresol-formalin treatments were repeated until no growth appeared on the culture media, *i.e.* until the canal was "sterile." The canal was then flooded with a saturated solution of paramonochlorphenol, the excess of moisture absorbed on fibers of asbestos which had been heated to a glow, and then the canal was pumped full of tricresol-formalin paste or Peruvian balsam-iodoform. The entrance to the canal was then covered with a piece of asbestos and the cavity closed with the zinc oxid-eugenol cement. After two or three up to twelve months these cases were again studied in practically the same way as at the start; variants from this procedure were carried out. The consideration of the most significant of these can be taken up under the

discussion of the general summary of Cevey's work, which follows:

(1) Zinc oxid-eugenol fillings (sealings) can confidently be relied upon to prevent ingress of bacteria from the saliva to the root-canal.

(2) An infected root-canal cannot be permanently sterilized with tricresol and formalin. The first dressings are in many cases infected even on the second day.

(3) The results are the more lasting, the more frequently are the tricresol and formalin dressings inserted.

The above statements (2) and (3) are in harmony with the conclusion of Brooks and Price (*DENTAL COSMOS*, June 1918, p. 532), to the effect that the efficiency of a root treatment is greater a few hours after it has been placed in the tooth than after several days' or even one day's time. (See Cevey's "Table 47," p. 259.)

(4) The results of Cevey's investigations in general agree in so far as they concern the treatment of pulpal gangrene and pericementitis in their acute and chronic forms with the results secured by Mayrhofer. Neither the tricresol-formalin nor the Peruvian balsam-iodoform methods meet the requisites which must from a bacteriological standpoint be exacted in root-canal treatment.

(5) The canals which have been treated with tricresol and formalin dressings and which have been maintained sterile were filled with either tricresol and formalin or Peruvian balsam and iodoform. Both procedures give about the same results.

(6) A permanent sterility cannot with certainty be secured with either method. After six months to a year micro-organisms could still be cultivated from about 25 per cent. of the treated canals.

(7) On the other hand, roots treated in this fashion remain generally at least a year without clinical symptoms.

(8) The radiographs taken after each canal filling show that in most cases tricresol and formalin paste or Peruvian balsam and iodoform cannot be carried to the apex.

(9) The disinfection of infected canals can more rapidly and with greater certainty be accomplished by a combination of tricresol and formalin with chlorphenol-thymol in vapor form.

Inasmuch as this method proved itself the

most efficient in Cevey's hands it will be desirable to describe it. The solution consists of equal parts of (1) saturated alcoholic solution of paramonochlorophenol and (2) a saturated alcoholic solution of thymol. After the tricresol and formalin treatment the canal is flooded with this solution. Then the fluid is vaporized by a long thin platinum needle by the thermocautery until the canal wall is completely dry and the patient feels a slight uneasiness, which indicates that the drying has been adequate. The canal is again moistened with the solution simply to facilitate the flowing of the tricresol and formalin paste into the canal for the permanent filling. Permanent filling with the Peruvian balsam and iodoform gave slightly better results. While this method proved itself better than the others tested by Cevey, still its results are by no means satisfactory. At best not more than 85 per cent. of the canals had escaped reinfection.

The relative success of this method is comparable with that of Cameron's (Brooks and Price, *DENTAL COSMOS*, June 1918, p. 532), by which at least as satisfactory clinical results are secured by the simpler technique of merely rapidly vaporizing a very dilute solution of formalin within the canal. The mode of applying disinfectants frequently to a large extent determines their efficacy, and it may be that the anatomical and chemical conditions as we find them in an infected canal demand the application of the disinfectant in a gaseous form.

Buisman (*DENTAL COSMOS*, September 1917, p. 929) has discussed the use of thymol as an agent for the filling of canals. In the April 1918 issue of the *Tijdschrift voor Tandheelkunde* he again takes up this topic. This article is mainly a critique, and contains little that differs from his former paper. However, he still maintains, within the limits already defined, that despite the occasional disappearance of thymol from the canal by sublimation (*cf.* Cameron's and Cevey's intentional vaporization) and possibly certain phenomena of irritation, his former favorable opinion of thymol is justifiable.

(10) In addition to pulpal gangrene simple cases of pulpitis were studied. A pulp was considered septic when, after the exercise of all aseptic precautions in removing it, it proved bacteriologically to be infected. Canals

from which have been extracted septic pulps should be treated just as are the cases of pulpal gangrene.

(11) Clinically it is impossible to distinguish between septic and aseptic pulpitis. Consequently a disinfectant treatment before canal-filling is to be advised in every case of pulpitis.

Baltimore, May 1, 1918.]

Behavior of Hypochlorite and of Chloramin-T Solutions in Contact with Necrotic and Normal Tissues *in vivo*.

Toxicity of Certain Widely Used Antiseptics. BY J. HAROLD AUSTIN AND HERBERT D. TAYLOR.

It has been known for some time that the chlorin content and consequently the potency of hypochlorite of soda solutions diminishes rapidly when in contact with the surface of wounds. The experiments were carried out upon lesions upon rabbit ears following exposure to the Coolidge tube. These ears were suspended, with normal ones, in (1) Dakin's hypochlorite solution of known strength, (2) an indifferent alkaline solution (sodium carbonate 1 gm. and sodium bicarbonate 17 gm. per liter of water), and (3) a solution of chloramin-T. After exposure to these solutions for varying lengths of time, the chlorin content was established by titration with sodium thiosulfate. Their conclusions follow: (1) The fall in chlorin concentration of Dakin's hypochlorite solution is more rapid in contact with necrotic than in contact with normal tissue. (2) The fall in chlorin concentration of chloramin-T solution is very slight when applied to necrotic tissue, and is negligible when applied to normal tissue. (3) The action of the hypochlorite solution on tissue results in the separation of particles of necrotic tissue, hair, epithelial scales, coagulated serum, etc., and a gradual digestion of these substances, taking place over a period of at least seventeen hours. (4) The fall in the chlorin concentration of the hypochlorite solution is not complete until the particles are completely dissolved. (5) Chloramin-T solution, 2 per cent., has no erosive effect comparable with that exhibited by the hypochlorite solution. (6) Repeated expo-

sures to the three solutions show the hypochlorite solution to be superior in its cleansing ability on necrotic tissue. (7) The hypochlorite solution is much more irritating to normal rabbit skin than chloramin-T solution or the alkaline control solution. (8) Therefore the irritating effects must be due to the readily available chlorin.

The second of the articles by the authors is pertinent in view of the widespread use of certain antiseptics in the treatment of infected wounds. Consequently it would seem desirable to make toxicity tests on animals under conditions in which rapid absorption might be expected. While, as a rule, the antiseptics are employed under conditions that preclude the possibility of much absorption with consequent systemic effect, yet occasionally certain of them have been recommended, and in some instances even used for injection into closed cavities where considerable absorption might occur. The method of the present study was to inject increasing doses into mice intraperitoneally, and into guinea-pigs both subcutaneously and intraperitoneally, and to note and tabulate the results. The conclusions drawn are: (1) The substances injected intraperitoneally into mice and guinea-pigs arranged in order of their decreasing toxicity are eucalyptol and brilliant green; mercuraphen; mercuric chlorid and chloramin-T; dichloramin-T and proflavine; hypochlorite, Dakin's hypochlorite, Javelle water, and magnesium hypochlorite; iodine and phenol. (2) Now that Dakin's bland solvent, chlorosane, is available as a vehicle for dichloramin-T, eucalyptol should probably be discarded for this purpose, because of its much greater toxicity. (3) Inasmuch as experienced surgeons do not approve of the injection of solutions of iodine and phenol into closed cavities, it would seem advisable not to use any of the antiseptics here discussed in this manner, inasmuch as all exhibit a greater toxicity for mice and guinea-pigs than the two chemicals first named. (4) The method of testing toxicity of antiseptics by subcutaneous injection is not satisfactory, because exudation and subsequent sloughing reduce the rate of absorption, and make uncertain the amount finally absorbed.

THE DENTAL COSMOS

A MONTHLY RECORD OF DENTAL SCIENCE.

Devoted to the Interests of the Profession.

EDWARD C. KIRK, D.D.S., Sc.D., LL.D., *Editor.*

L. PIERCE ANTHONY, D.D.S., *Associate Editor.*

PUBLISHED BY THE S. S. WHITE DENTAL MFG. CO., PHILADELPHIA, PA.

SUBSCRIPTION PRICE, including postage, \$1.00 a year to all parts of the United States, Hawaiian Islands, the Philippines, Guam, Porto Rico, Virgin Islands, Cuba, and Mexico. Canada, \$1.40. To other foreign countries, \$1.75 a year.

Original contributions, society reports, and other correspondence intended for publication should be addressed to the EDITOR, Lock Box 1615, Philadelphia, Pa.

Subscriptions and communications relating to advertisements should be addressed to the BUSINESS MANAGER of the DENTAL COSMOS, Lock Box 1615, Philadelphia, Pa.

PHILADELPHIA, AUGUST 1918.

EDITORIAL DEPARTMENT

The Status Praesens.

WE publish in this issue at page 733 the text of the Act of Congress reorganizing the Navy Dental Corps, reconstituting its grades with their respective pay and allowances, and establishing its status with respect to the Medical Corps of the Navy. With slight amendment the present law is the enactment of the bill which was introduced in the Senate by Senator Tillman and in the House by Representative Dyer. Its outstanding feature is its official recognition of the principle of equality of status within the respective grades of dental and medical service, the same principle which characterized the Act of Congress of October 6, 1917, with respect to army dental service. The dental profession is again to be congratulated upon the achievement of this epoch-making step in the history of its progress—epoch-making in the

sense that our national Government has set the seal of its official approval on the principle that dentistry is within its sphere entitled to the same recognition that it accords to all other departments of the science and art of healing. As we noted in our issue for April of this year in connection with the enactment of the present navy dental law, the Government recognition thus finally attained, is the outcome of upward of sixty years of more or less continuous effort upon the part of the dental profession to secure a proper understanding and adequate recognition of its inherent right to a place commensurate with its importance among the specialties of the healing art. The principle involved might have been established earlier had this legislative effort not had its course beset from time to time with the ambitious interference of those who held their personal interests as paramount to the professional welfare. More is yet to be accomplished before the status of the dental surgeon, both in the army and the navy, and the full efficiency of their service to the defensive forces of the nation, can be practically realized.

The present law, while it equalizes the status of dental surgeons and surgeons within a defined classification, limits the grades assigned to the dental surgeon and retains dentistry as a department under medical control. The future legislative program should aim at establishing additional grades in the dental corps to equalize it with the medical and other staff corps, and especially at the increase in the ratio of dental officers to such an extent that dental treatment will be universal and complete for the *personnel* of the Navy and Marine Corps; and ultimate separation of the dental corps in both army and navy from direct jurisdiction by the medical corps. These are objectives to be achieved in the future as growth and maturity in dentistry and in its service to the military arm justify their attainment. Recognition is sure to follow as the justification of service honestly and adequately rendered; what we have already gained is evidence of the truth of that assertion.

The exigencies created by the present war conditions have created the golden opportunity for dentistry to demonstrate the value of its service, and to its everlasting credit be it said, dentistry is responding promptly, loyally, and efficiently. Despite the wholly inadequate allotment of dental surgeons to the army and

navy *personnel* and the corresponding limitations to a complete dental treatment of those called to the nation's defense, the Army and Navy Dental Surgeons corps have rendered a splendid service and one of inestimable value and importance not only in relieving the many disabilities arising from defective teeth and mouth conditions; but what is more important though not by any means so obvious, the Dental Surgeons Corps has done its full share in maintaining the high standard of physical welfare of our troops, by eliminating, in so far as it has been physically possible to do so, infected mouth conditions which are the source of a long list of bodily ills.

The insufficiency of the present ratio of dental surgeons allotted to the army and navy *personnel* is self-evident. Recommendation by the dental committee of the Council of National Defense for a larger ratio of dental surgeons was made soon after the United States entered the war, and that the need for a larger corps is a real one in order that complete dental care may be available for the whole army and navy is evidenced by the emphasis placed upon the need of a larger dental corps by Representative Dyer in his argument in favor of the bill recently passed reorganizing the Navy Dental Corps. The most striking and practical evidence of the need for more thorough dental treatment for the army and navy *personnel*, and incidentally an equally striking example of the loyalty and enthusiastic support which the dental profession has been and is contributing to the winning of the war, is the magnificent and unselfish work being carried on by the Preparedness League of American Dentists. Through the intuition, personal enthusiasm, and devotion of Dr. J. W. Beach of Buffalo, the great possibilities of the service which civilian dentists could render in the preparation of recruits for military duty were clearly foreseen, and an organization with that object in view was started, at first in a modest way, in the early days of the war. A general appeal for volunteers followed, and so enthusiastic was the response that the largest organization in the history of American dentistry sprang into existence in a few brief months. Today the more or less incomplete returns show a record of upward of a half million dental operations performed by members of the League gratuitously for recruits entering the service. And the work is still going on in an increasing ratio.

Dentistry has in times past been subjected to criticism, justly or unjustly as the case may be, for its lack of willingness to render a public professional service without adequate compensation. Whatever may have been the case in the past, the practical evidence of the patriotic altruism of dentistry in the present world conflict is an indisputable refutation of that type of criticism now and for the future. The spirit in which the service is rendered is equally beyond criticism, for it is given not in the hope of reward in any material sense, but as the recognition of an opportunity to demonstrate the importance and value of our ministrations in conserving the health of those engaged in the national defense, and equally its importance to the health of the nation itself.

The events of our era are making history at a rapid rate. At no time in the past has dentistry developed so rapidly or been accorded in such large degree distinct recognition as one of the essentials of public health. Opportunity has knocked at her door and found her waiting; and, facing the future with a reasonable conservatism but with an abiding faith in the possibilities of her humanitarian service, dentistry is confidently approaching the fulfilment of the prophecy of Mayo by preparing to "take the next great step in preventive medicine"—toward the consummation of which all of her energies are now directed.

PERISCOPE

Spacing Between Natural and Artificial Teeth.—When spaces between teeth are desirable, let the spaces be between the artificial teeth rather than between artificial and natural ones. A group of porcelain teeth set closely together and separated by a space from an adjoining natural one would be apt to exaggerate and draw attention to those small differences in appearance between natural tissues and substitutes, differences which are more or less unavoidable. And it is better to have contiguous natural and artificial

teeth arranged in correct approximal contact for two additional reasons, one being directly functional in protecting the gum and preventing the impacting of food, and the other being indirectly functional, inasmuch as the steadiness and retention of a denture is considerably increased by exact approximal contact between natural teeth and substitutes, which contact should be carefully preserved when adjusting and fitting the finished case in the mouth.—D. MACKINTOSH SHAW, *Dental Record*.

Setting Crowns and Bridges.—Evans' gutta-percha is one of the most valuable materials that we have in our office, and I have found that comparatively few dentists have ever used it. With it it is possible to set crowns and bridges as firmly as with cement, and yet they can be removed with ease.—O. D. DAVIS, *Dental Review*.

A Good Separating Medium for Plaster Impressions.—Having tried many of these, I have found none so quick and satisfactory as a solution of paraffin wax in petrol. It is clean to handle, always ready, and the impression can be painted over and cast within a few minutes after being taken.—H. J. MORRIS, *Ash's Journal*.

To Sterilize Dentin.—Before inserting a filling or cement base in a tooth in which the pulp is alive, evaporate a 15 per cent. solution of thymol in alcohol in the cavity. The thymol will penetrate the tubuli and sterilize the dentin. This will avoid irritation of the pulp, which may cause secondary dentin, pulp nodules, or even death to the pulp.—A. DE VRIES, *Dental Review*.

To Refit a Rubber Plate Without Vulcanizing.—Smear the plate with plaster, place in the mouth, and when hard remove. Pour a model. Remove the plate and also its plaster covering. Having had the shot of a Parker shot-swager in boiling water, or preferably glycerin, place the plate upon the model and embed in the swager. Do not hammer, but place a heavy weight upon the piston. Remove when cold.—L. E. CUSTER, *Dental Summary*.

Sensitive Dentin.—I never expose freshly cut dentin to the fluids of the mouth when I can help it, and whether I do or do not, I treat it to a touch of oil of cloves. Treating the cavity with alcohol followed by oil of cloves warmed with a puff of hot air from your chip-blower, and the cavity stopped with gutta-percha until the patient returns, will prevent the sensitiveness sometimes complained of after setting an inlay. Not only that, but pulps are not so likely to die.—HOMER ALMON, *Dental Review*.

Root-end Encapsulation.—When we come to the question of root encapsulation, there is where Dr. Rhein and I part company, because I do not believe in it. I do not believe in it because it is inconceivable to me, in the first place, that in any considerable percentage of cases a complete encapsulation of the denuded root-end with gutta-percha is

possible, and secondly, I do not believe that the gutta-percha is any improvement over the root-end so far as healing is concerned.—ARTHUR D. BLACK, *Dental Review*.

To Prevent Broaches from Falling into the Throat.—If one is using a root-canal reamer in the fingers and working in the canals of a tooth upon which it is difficult (or impossible) to place the rubber dam and holder, use a sheet of Japanese bibulous paper folded between the teeth and tongue and allowed to extend toward the throat, and it answers the purpose of a rubber dam nicely; when wet, use another.—M. J. LINDERHOLM, *Farmington, Iowa*.

Spatulation of Silicate Cement.—Spatulation beyond the point of thorough and homogeneous incorporation of the powder and liquid is not necessary, though contrary instructions have been sent out with one of the silicate cements. It is desirable to put a larger portion of powder into the liquid at first, rather than to begin with small portions and increase. The first portion of powder put into the liquid should be as much as can be immediately and quickly incorporated with it, and successive portions smaller.—EDMUND NOYES, *Dental Review*.

To Avoid Air-bubbles in Plaster Casts.—After coating the impression with separating medium apply a moderately thin mix of plaster to the entire surface of the impression with a $\frac{1}{2}$ -inch oval paint-brush (not camel's hair). When coated, immediately immerse the brush in a glass of water, and finish pouring the cast in the usual manner. This avoids jarring the impression with probably fracture or distortion. Allow the brush to remain in water. When necessary to use it again the plaster will shake or jar out readily, and the brush is as clean as when new.—LESTER N. ROUBERT, *Dental Review*.

Finishing Dentures.—Many mechanics still spend much time and labor with files and scrapers over this work. It can, however, be greatly reduced. To begin with, the use of a piece of thin soft metal burnished over the wax will give a good surface in the most inaccessible part of the palate. Instead of filing the edges of the newly vulcanized plate, they are heated in the gas, and with a sharp knife can be pared down as rapidly as if they were cheese, and that without the slightest fear of warping them, because the heat is localized, vulcanite being a very bad conductor. The edges and surfaces can be

rapidly finished with a fine sandpaper arbor in the lathe, and with a little more trimming around the teeth the piece is ready for the final polishing. Large rosehead burs with the upper half of the sphere ground off are most useful in the workroom engine for trimming difficult places, and for doing quick and neat repairs. A small thin stone with a blunt edge is also a great help for finishing the embrasures between molars on the palatal aspect.—H. J. MORRIS, *Ash's Journal*.

Bismuth Salicylate for Root-filling.—Instead of chloro-percha I have used for twenty years for root-filling a paste made of bismuth salicylate and oil of cajuput. The oil is a solvent for gutta-percha. The bismuth comes as nearly being a permanent antiseptic as anything you can use. Be sure to get the salicylate instead of the subsalicylate, the latter being so light that it will not mix to a smooth creamy paste. Mix on a slab for each case.—F. C. NOYES, *Dental Review*.

Variation in the Size of Teeth in the Same Jaw.—It has been my experience that the teeth of one jaw do not harmonize with those of the other in size except in rare cases. I want to go farther, and say that the lateral halves of the arches do not correspond in the measurement of the teeth. There is the greatest latitude there. I had one case where one central incisor was three millimeters wider than its mate. I can show you bicuspids from one to one and one-half millimeters wider than the corresponding bicuspids on the other side. It is rather rare to find cases where the lateral halves of the arch correspond in measurement. It is the great latitude which we have in the amount of overbite that permits us to get anything like normal occlusion.—RAY ROBINSON, *Dental Items of Interest*.

"Hard" and "Soft" Teeth.—A careful observation of the phenomenon presented by the difference in the behavior of teeth under cutting instruments will reveal the fact that this difference is confined for the most part to the enamel, and that it does not relate to any variation in the chemical constituents of the teeth, but to the mere mechanical fact of the difference in the arrangement of the enamel rods. As everyone in the profession knows, the enamel rods stand with one end resting on the dentin, and from this radiating out toward the external surface of the crown of the tooth. It is the particular manner of this radiation that controls the resistance or lack of resistance of the enamel to cutting instruments. In some instances the rods

radiate in a straight, regular, and almost parallel manner, while in others they pursue a wavy irregular course; this difference in the arrangement of the rods making the difference between enamel which cleaves easily and that which resists the instrument. It is well illustrated by the homely example of the difference between splitting straight-grained maple and bird's-eye maple. Every boy brought up in the country knows what a joy it is to split straight maple as compared with the difficulty attached to the attempt to split bird's-eye.—C. N. JOHNSON, *Dental Review*.

Precautions in the Use of Silicate Cement.—While the silicate is in the plastic state it is not hydraulic. This is due to the fact that the formation of the insoluble hydrated phosphates from the soluble acid phosphates requires some time for its completion. Hence, in order to avoid the solvent action of moisture at this stage some precautions should be observed.

(1) The tooth should be isolated by the rubber dam.

(2) The cavity should be dry. These simple methods will prevent any solution of the soluble salts before they have had the time necessary to convert them into insoluble ones.

(3) Inasmuch as the silicate undergoes a secondary hardening accompanied by a marked change in physical properties, in order to obtain the best possible results the filling should be coated with a varnish or other waterproof coating, which will prevent moisture from interfering with its proper crystallization.

One would not use a garden hose on a cement walk until at least twenty-four hours after it had been placed, so why should we permit water to come in contact with a silicate filling, the secondary hardening of which is analogous to that of Portland cement, until that filling has been allowed the same length of time for the final step in its hardening.—C. C. VOGR, *Dental Review*.

Preparation of the Tooth at the Gum Margin for a Porcelain Jacket Crown.—The enamel rod direction at the gingival border under the free margins of the gums compels us to remove the enamel entirely, if we are to have a perfect shoulder. Were we replacing it properly or not was a question. You can easily see that the thickness we remove and the amount we replace would have a bearing upon the tension given the soft tissues. I took a set of teeth and cut the

crown off 1 mm. from the gingival line, measured each surface, and cut off $\frac{1}{2}$ mm. more. I found that the enamel varied in thickness upon each surface, and this variation was constant. It is impossible to reproduce this variation in thickness in a single banded crown, even if the different thickness of enamel on each surface was known.

The shoulder is cut with a plain fissure bur, starting at the labio-gingival angle and cutting across the labial. Then start at the center of the lingual, cut to the mesial, and through the approximal, joining the labial shoulder. Start again on the lingual, cut to the distal through the approximal, and join the labial again. The finished shoulder should be about $\frac{1}{2}$ mm. wide, well under the free margin of the gum. A further refinement of the shoulder is made with a special set of instruments, cutting it so that it will incline inward and upward slightly toward the apex. This is an important detail.—GEORGE A. THOMPSON, *Dental Review*.

The Advantages of Nerve-blocking Anesthesia.—The advantages of nerve-blocking anesthesia for oral and dental surgery operations are many, but the following are probably the most important:

(1) The duration of the anesthesia may be changed according to the various amounts of the vaso-constricting agent. The long duration of anesthesia is of great value to the operator for the removal of impacted third molars, draining the antrum, root amputation, removal of tumors, removal of cysts, resection of the jaw, curetment of necrosed bone, plastic operations, removal of tonsils, and many other operations which come under the observation of the oral surgeon.

(2) Long duration of anesthesia permits the operator to take his time with the operation, which gives him the opportunity to employ all his skill when operating.

(3) Large or small areas may be anesthetized, depending upon the nerve or nerve branches blocked.

(4) Anesthesia is secured in infected or inflamed areas by blocking the nerve branch in healthy tissue at a distant point from the operative field.

(5) Nerve-blocking injections, when skillfully made, are without pain, because the needle is inserted into the mucous membrane and loose connective tissue.

(6) One or two insertions of the needle will block an operative field, depending upon the nature of the operation and the area to be blocked.—ARTHUR E. SMITH, *Dental Review*.

The Teeth as Foci of Infection.—The ruthless extraction of teeth, as demanded by some of the physicians, is a crime against the patient, an indictment against the physician and the surgeon, and a sad commentary on the co-operation and understanding existing between the medical and dental professions. The mechanics of dentistry, the locating and cure of oral focal infection is outside of the physician's field, but it has taken the physician to point out to us that our modern dentistry, so perfect in a sense in its mechanics, is a menace to our patients' health and lives, and we must recognize the fact that our work has a very much farther influence on our patients' systemic condition for good or ill than we have dreamed. But let us not be stampeded into the belief that our treatments of teeth are the cause of all the troubles in the world. I think possibly our failures are not nearly as many or as grievous as the X-ray paints them. We have found that we get apical infections from the blood stream. Some surgeons demand that all infections be removed before they operate. Treating a tooth is a surgical operation. How would it be if we demanded that all focal infection be cleaned up before we devitalized? How do we know that many of these apical abscesses are not secondary in place of primary? Is it not reasonable that they are? How can you expect to get perfect results from treatments when the blood is filled with streptococci from tonsils, sinuses, gastric ulcers, etc.? So in place of being the arch sinner, maybe the teeth are the most sinned against organs in the body.—CHARLES A. PEAK, *Dental Summary*.

Technique of Root-end Encapsulation.—Base-plate gutta-percha has been found the most suitable material for root-filling, and especially for encapsulating the end of the root, because of its compatibility with the human tissues and its unchangeable nature as far as contraction or expansion is concerned.

Having reached the point in the operation where the root-canal in a thoroughly aseptic state has been dried out and ready for filling, chloro-percha made by dissolving base-plate gutta-percha in chloroform is introduced in very fluid form into the canal, which is not only filled with it, but the material is pumped through the foramen. A point of gutta-percha, the diameter of which is the same all the way through, is now carried to the end of the canal, and there macerated by packing it with fresh chloroform. In this softened cheesy condition, it is now by compression forced through the foramen, and this

soft cheesy mass is immediately thrown back around the side of the root. The chloroform volatilizes with such rapidity that the root surface under it is dehydrated, and as a result the softened gutta-percha remains firmly adherent to this surface, whether or not covered with pericementum. Such is the ideal physical condition that takes place. This method is found more successful than the one formerly used of endeavoring to force the hard gutta-percha cone through the foramen. In this hardened state the cone has a tendency to protrude like a cork through a bottle, on account of its rigidity. Such a result will bring thorough success when there is only a simple foramen, but where we have multiple foramina it generally spells failure of the operation.—M. L. RHEIN, *Dental Review*.

Arch Form.—For a given set of teeth there exists not only one arch form which complies with our known rules of occlusion, but an indefinite number of them. If only one form existed, it would be a matter of mere chance for any one man to predetermine it.

That means we should endeavor to reconstruct that arch form which most likely will conform to given conditions. This predetermined arch form is subject to changes because we are limited to a great extent in making accurate measurements. If we were able to introduce absolutely correct measurements (which we cannot do) and had absolute and full knowledge of all requirements that make occlusion and mastication perfect (which is not the case), then we would be able to reconstruct an arch form best suited for a given set of teeth in the mouth. That such an arch form is the one nature intended, can hardly, however, be claimed.—RUDOLPH L. HANAU, *Dental Items of Interest*.

Care of the Toothbrush.—Many articles have been published in the dental journals on the septic state of the toothbrush as ordinarily cleaned before and after use, and advising how to treat it to produce a nearly sterile condition. Manufacturers of dental pastes and mouthwashes have showered the profession with circulars, claiming efficiency for their products to make the brush sterile, and proving it to their satisfaction by comparative tables of bacterial counts from cultures made from brushes, before and after the brushes have been in contact with their own mouthwash or paste. It is not in my recollection that boiling water has been recommended for that purpose. It may have been, but I have never found it in the journals.

This may be owing, perhaps, to a supposition that boiling water injures and destroys the brush, which in my experience has not proved to be the case. Have a kettle of water on the gas or other heater; before brushing the teeth, pour generously of the water, when boiling, over the brush; after brushing the teeth pour boiling water again over the brush before putting it away, preferably in some closed container. After cleaning the teeth with floss and brush, rinse the mouth with tepid or warm water, which will remove the loose foreign particles better than cold water, which has a tendency to make them adhere.

This treatment of the brush with boiling water seems not to injure it. I have subjected my present brush to it for at least six months without damaging it in the least. I have made no laboratory experiments to determine the comparative efficiency of the method; it seems to me, however, that a germ that has had boiling water poured over it would be a pretty sick germ, disinclined for immediate mischief.

This method of course is practicable only where access is had to boiling water.—VINCENT FISCHER, *Dental Review*.

Apothesine.—A reliable local anesthetic has become one of the essentials in present-day operative dentistry. The disuse of novocain has forced itself on to the dental profession by reason of prohibitive cost and scarcity in this country.

About six months ago I began the use of apothesine, an American-made product, and it has apparently fulfilled all the requirements of an anesthetic. I have used it for more than five hundred cases of extraction; of this entire number ten applications were followed by more or less sloughing, but only two of these required any subsequent attention. The ten cases to which I refer included abscesses, ulceration, pyorrhea, and highly congested or flabby tissues. They were all observed in unclean and neglected mouths. No sloughing or irritation was observed in cases presenting anything like a normal condition of the gums.

In referring to the general use of a local anesthetic, based upon wide experience, it is my opinion that the undesirable and annoying conditions that sometimes follow infiltration anesthesia are due to faulty technique, or exceptionally unfavorable condition of the tissue. It is not reasonable to expect a prompt infiltration of any fluid in deeply congested gums. When injecting an anesthetic solution into such tissue the quantity should be as small as possible to produce the desired anes-

thetic effect, and may require a wider distribution of injections than in reasonably normal and healthy structures. It will also require a longer time for complete anesthesia to be effected. Where too much fluid is injected into a highly congested tissue, some destruction of the parts may be anticipated following extraction, especially if there is much trauma from the operation. This will

vary according to the technique employed and the conditions with which the operator is working. Very embarrassing conditions may be produced by any aqueous solution, or even sterile water, although some operators may be tempted to lay the blame to the anesthetic agent. This is unfair both to the operator and to the agent employed.—PAUL J. GLUGLA, *Michigan Dental Journal*.

OBITUARY

Dr. Thomas Cook Stellwagen.

[SEE FRONTISPIECE.]

DIED, Friday, June 7, 1918, at the home of his daughter, Media, Pa., from diabetes, in his seventy-seventh year, THOMAS COOK STELLWAGEN, D.D.S.

Dr. Stellwagen was born in Philadelphia, Pa., July 24, 1841, the son of U.S.N. Capt. H. S. Stellwagen and Mary (Cook) Stellwagen. Dr. Stellwagen obtained his early education in the public schools of Philadelphia, and was graduated from the Philadelphia Central High School in 1859, receiving the A.B. degree. He received the M.A. degree in 1864.

At the age of eighteen years Dr. Stellwagen became interested in dentistry, and in 1859 began its study under the preceptorship of Dr. N. L. Dickey of New Orleans, La. Later he entered the Pennsylvania College of Dental Surgery, and was graduated from that institution with the D.D.S. degree in 1861. In 1866 he also received the D.D.S. degree from the Philadelphia Dental College, and continuing his professional education, he received the M.D. degree from the University of Pennsylvania in 1868. Upon the completion of his professional education, Dr. Stellwagen began the practice of dentistry in Philadelphia, and continued in active practice until 1912, when he retired.

At the outbreak of the civil war, Dr. Stellwagen enlisted in the United States navy, and acted in the capacity of paymaster upon the U.S.S. "Mercedita," which was commanded

by his father, Henry S. Stellwagen, during the civil war. The vessel on which Dr. Stellwagen served was in several engagements during the civil war, and did blockade duty until 1863. He was later transferred to the U.S.S. "Constellation," on which ship he served until the close of the war.

In 1865 he resigned from the United States navy and resumed his practice in Philadelphia, accepting the demonstratorship of operative dentistry in the Philadelphia Dental College, from which institution he received the *ad eundem* degree in 1866. In 1869 he was elected to the chair of dental histology and operative dentistry in the above institution. In 1879, upon the death of his life-long friend, Prof. John H. McQuillen, the founder of the college, Dr. Stellwagen was made professor of physiology, which professorship he held for many years.

At the beginning of his professional career, Dr. Stellwagen took a lively interest in dental societies, and was one of the organizers of the Odontographic Society of Pennsylvania and the Pennsylvania State Dental Society, being elected corresponding secretary of the State Society at its meeting of organization. He later in 1899 served the State Society as president. He was a member of the American Academy of Dental Science, the Pennsylvania Association of Dental Surgeons, a corresponding member of the Odontological Society of Great Britain, a member of the Academy of Natural Science of Philadelphia, and of the Franklin Institute.

Dr. Stellwagen was a conspicuous member

of the group of dentists in America which followed very closely the pioneers of dentistry in this country, and did much to maintain the high professional standing of dentistry at the time when Philadelphia established its name as the "home of dentistry." He was always dignified and courteous in his manner, and was ever held in the highest esteem by his professional associates and by all who were privileged to know him professionally and socially.

Dr. Stellwagen made many contributions to the literature of dentistry, notably among which was his revision and editing of "Coleman's Manual of Dental Surgery and Pathology" for the American profession in 1882.

Dr. Stellwagen was married, in Philadelphia, March 5, 1868, to Miss Annie Eliza Carpenter. He is survived by his son, Major Thomas C. Stellwagen, Jr., and five daughters.

THE following in *memoriam* resolutions on the death of Dr. Stellwagen were adopted by the Academy of Stomatology of Philadelphia:

Whereas, death has removed from us our esteemed friend and fellow member, Thomas C. Stellwagen; therefore be it

RESOLVED, That the Academy of Stomatology, of which he was an honored member, recognizing his long and useful career and his great worth as a teacher and contributor to dental literature, desires to express its sorrow for his loss, and to extend to his family this expression of sincere sympathy in their great bereavement; and be it also

RESOLVED, That these resolutions be placed upon the minutes, a copy sent to the bereaved family, and that they be published in the DENTAL COSMOS.

ROBERT HUEY,
M. H. CRYER,
W. STIRLING HEWITT,
Committee.

Dr. Henry B. Nones.

DIED, Wednesday, May 1, 1918, at his home in Philadelphia, Pa., in his forty-eighth year, after an illness of several months, HENRY BENJAMIN NONES, D.D.S.

Dr. Nones was born in Philadelphia on December 6, 1870, the son of the late Dr. Samuel Smith Nones and Harriet (Hodgson) Nones. Dr. Nones received his early educa-

tion in the public schools of Philadelphia, and later entered the Philadelphia Dental College, from which institution he was graduated in 1891.

Dr. Nones came from a family three generations of which have been dentists. He was for several years chief demonstrator of mechanical dentistry in the dental department of the Medico-Chirurgical College of Philadelphia, of which institution his brother, Dr. Robert H. Nones, was dean at the time, and with whom he was associated in practice for about twenty-five years.

Dr. Nones married Miss E. Florence Slater, who with his brother, Dr. Robert H. Nones, his sister, Miss Ida Wiley, and a half-brother, Albert Nones, survives him.

Dr. Louis A. O'Brian.

DIED, Tuesday, June 4, 1918, at his home, Harmon-on-the-Hudson, in his fifty-fifth year, from septic poisoning, LOUIS A. O'BRIAN, D.D.S.

Dr. O'Brian was born in Providence, R. I., in 1863. He obtained his early education in the public schools of Providence, later being graduated from the Brown University. In 1886 he entered the Philadelphia Dental College, from which institution he was graduated in 1888. Soon after his graduation Dr. O'Brian went to Paris to practice his profession, later removing to Dresden, Germany, where he conducted his practice until 1903, numbering among his *clientèle* in Dresden the Crown Prince Louis of Saxony and many others of the royal family. Dr. O'Brian returned to the United States in 1903, and established himself in New York City, where he continued to practice until the time of his death.

Dr. O'Brian was a member of the National Dental Association, the First District Dental Society of the State of New York, a member and at one time president of the American Dental Society of Europe, a member of the faculty of the Flower Hospital Medical College of New York, and attending dentist to the New York Surgical, Throat, Nose, and Lung Hospital.

Dr. O'Brian is survived by his widow and two sons.

DENTAL LEGISLATION

AND

LEGAL DECISIONS.

Naval Appropriation Bill—Provision for the Naval Dental Corps.

[AMENDMENT NO. 23, AS AMENDED.]

THE provision for the Naval Dental Corps (Amendment No. 23), was amended to read as follows:

That the Act approved August 29, 1916, entitled "An Act making appropriation for the Naval Service for the fiscal year ending June 30, 1917, and for other purposes" (Statutes at Large, vol. 39, chapter 417, pp. 573, 574), be, and the same is hereby, amended by striking out all of said Act following the caption "Naval Dental Corps," on page 573, but preceding the caption "Dental Reserve Corps" on page 574, and by substituting therefor the following:

That the President of the United States is hereby authorized to appoint and commission, by and with advice and consent of the Senate, dental officers in the Navy at the rate of one for each thousand of the total authorized number of officers and enlisted men of the Navy and Marine Corps, in the grades of assistant dental surgeon, passed assistant dental surgeon, and dental surgeon, who shall constitute the Naval Dental Corps, and shall be a part of the Medical Department of the Navy. Original appointments to the Naval Dental Corps shall be made in the grade of assistant dental surgeon with the rank of lieutenant (junior grade) and all dental officers now in the dental corps appointed under the provisions of the Act of Congress approved August 22, 1912 (Stat. at L., ch. 37, p. 345), or under the provisions of the Act of Congress approved August 29, 1916 (Stat. at L., ch. 39, p. 573), or may hereafter be appointed, shall take rank and

precedence with officers of the Naval Medical Corps of the same rank according to the dates of their respective commissions or original appointments, and all such dental officers shall be eligible for advancement in grade and rank in the same manner and under the same conditions as officers of the Naval Medical Corps with or next after whom they take precedence, and shall receive the same pay and allowances as officers of corresponding rank and length of service in the Naval Medical Corps up to and including the rank of lieutenant-commander: *Provided*, That dental surgeons shall be eligible for advancement in pay and allowances, but not in rank, to and including the pay and allowances of commander and captain, subject to such examinations as the Secretary of the Navy may prescribe, except that the number of dental surgeons with the pay and allowances of captain shall not exceed 4½ per cent. and the number of dental surgeons with the pay and allowances of commander shall not exceed 8 per cent. of the total authorized number of dental officers: *Provided further*, That dental surgeons shall be eligible for advancement to the pay and allowances of commander and captain when their total active service as dental officers in the Navy is such that if rendered as officers of the Naval Medical Corps it would place them in the list of medical officers with the pay and allowances of commander or captain, as the case may be: *And provided further*, That dental officers who shall have gained or lost numbers on the Navy list shall be considered to have gained or lost service accordingly; and the time served by dental officers on active duty as acting assistant dental surgeons and as-

sistant dental surgeons under provisions of law existing prior to the passage of this Act shall be reckoned in computing the increased service pay and service for precedence and promotion of dental officers herein authorized or heretofore appointed.

All appointees authorized by this Act shall be citizens of the United States between twenty-one and thirty-two years of age, and shall be graduates of standard medical or dental colleges and trained in the several branches of dentistry, and shall, before appointment, have successfully passed mental, moral, physical, and professional examinations before medical and professional examining boards appointed by the Secretary of the Navy, and have been recommended for appointment by such boards: *Provided*, That hereafter no person shall be appointed as assistant dental surgeon in the Navy who is not a graduate of a standard medical or dental college.

Officers of the Naval Dental Corps shall become eligible for retirement in the same manner and under the same conditions as now prescribed by law for officers of the Naval Medical Corps, except that section 1445 of the Revised Statutes of the United States shall not be applicable to dental officers, and they shall not be entitled to rank above lieutenant-commander on the retired list, or to retired pay above that of captain.

All dental officers now serving under probationary appointments shall become imme-

diately eligible for permanent appointment under the provisions of this Act, subject to the examinations prescribed by the Secretary of the Navy for original appointment as dental officers, and may be appointed assistant dental surgeon with the rank of lieutenant (junior grade) to rank from the date of their probationary appointments: *Provided*, That the senior dental officer now at the United States Naval Academy shall not be displaced by the provisions of this Act, and he shall hereafter have the grade of dental surgeon, and the rank, pay, and allowances of lieutenant-commander, and he shall not be eligible for retirement before he has reached the age of seventy years, except for physical disability incurred in the line of duty: *Provided further*, That no dental officer in the Navy who on original appointment as dental officer was over forty years of age shall be eligible for retirement before he has reached the age of seventy years, except for physical disability incurred in the line of duty.

All acts or parts of acts inconsistent with the provisions of this Act relating to the Dental Corps of the Navy are hereby repealed: *Provided*, That nothing herein contained shall be construed to legislate out of the service any officer now in the Medical Department of the Navy, or to reduce the rank, pay, or allowances now authorized by law for any officer of the Navy.

Approved.

Decisions in Patent Litigation.

Cassius M. Carr Patent Void.

UNITED STATES COURT DECRIES PATENT ON PYORRHEA TOOLS INVALID.

DENTISTS everywhere will be interested in learning that certain litigation of great importance to the profession has just terminated. The result is a complete victory for the Dental Protective Association of the United States, which, in carrying out the objects of its charter, successfully assumed the defense of a case brought against one of its members.

The Carr School of Preventive Dentistry and Medicine, assignee of Cassius M. Carr, brought suit against Dr. Austin F. James of Chicago, in the U. S. District Court for the

Northern District of Illinois, Eastern Division, for alleged infringement of the Carr patent on pyorrhea tools and for unfair competition in trade. On Tuesday, July 2, 1918, His Honor Judge GEORGE A. CARPENTER entered a final decree adjudging as invalid, void, and of no effect in law those letters patent known as No. 1,138,355, issued May 4, 1915, to Cassius M. Carr, on dental tools, and which the patentee purports to exemplify in a set of one hundred and fifty tools, well known as the "Carr pyorrhea set." The suit was

ordered dismissed for want of equity, at the plaintiff's costs.

The importance of the case arises from the establishment of the right of all dentists to avail themselves of instruments of the type described in the patent, in larger or smaller sets, without paying patent tribute to anyone. The Dental Protective Association of the United States conceived that the patent sued on was not a good patent in law, and that its existence could be made, and was likely to be made, the basis of serious oppression to dentists, especially in view of the numerous suits already brought under it. The suit against Dr. James was one which the association considered to be of that character. The Dental Protective Association has consistently fought to protect its members from unjust and unlawful patent claims, and makes no distinction in this respect between patents for mechanical devices and patents for processes or methods. While its chief obligation is to its members, such results as come from its success in the present case will inure to the benefit of the profession as a whole.

A vast amount of testimony was taken by both parties to the suit, the plaintiff having

thirty-six witnesses and the defendant twenty-five. For the defendant a large number of the most prominent teachers and practitioners on the subject of pyorrhea gave valuable testimony.

The defeat of the Carr patent ought to relieve many dentists from the annoyance of litigation which Carr or the Carr School has threatened to institute. The air is cleared, and dentists now are justified in treating the patent as though it did not exist.

In passing it may be mentioned that a suit brought by Carr against Dr. Thomas B. Hartzell of Minneapolis, on the same patent, was defended by the Dental Protective Association, and was also dismissed at Carr's costs.

The association's attorneys are Mr. Percy B. Eckhart of Chicago, general counsel, and Mr. Luther Johns of Chicago, patent counsel. We express our appreciation of the very thorough preparation of the case and its successful defense.

[Signed] J. G. REID,
D. M. GALLIE,
J. P. BUCKLEY,
Directors,
Dental Protective Association.

Dentists' Mutual Protective Alliance Wins in Taggart Case.

DECISION IN THE FEDERAL COURT, NORTHERN DISTRICT OF ILLINOIS.

ON March 4th. Judge F. A. GEIGER, of the Federal Court for the Northern District of Illinois, filed a decision which closed the longest and hardest chapter in the history of the litigation involving the Taggart cast-inlay patents. The thirteen cases just decided by Judge Geiger will now go to the highest Court of Appeals, where the final chapter will be written.

The case has been in the courts nearly three years. On certain points it was at one time appealed to the Appellate Court, which in June 1916 sustained the Alliance and confirmed Judge Geiger, and referred the case back to him for trial. Final arguments were made in April 1917.

Judge Geiger's decision is voluminous, covering some thirty-two typewritten pages, and is regarded as a complete victory for the Alliance.

Dr. Taggart's infringement suits against the thirteen practicing dentists of Chicago were selected from five hundred and twenty-three (523) similar suits to be defended by the Dentists' Mutual Protective Alliance in order to secure a final and conclusive adjudication upon any and every question which could arise under any of the four Taggart patents. Every one of the questions raised by the attorneys for the Alliance or the attorneys for Dr. Taggart is now decided in favor of the defendants, who were sued for an injunction and for profits and damages.

The four Taggart patents cover every phase of the production of a cast inlay from the formation of the wax pattern to the setting of the casting. The patents contain forty-six claims covering all of the steps of the process, all of the apparatus, including rings, flask-covers, sprue-formers, etc., and the prod-

ucts resulting at the various stages of the process—such, for example, as the wax pattern itself, the mold, and the final casting.

Every dentist who makes or sets a cast inlay filling infringes a majority of the claims of the Taggart patents. There was no question that the defendants in these thirteen test cases infringed many claims of the several patents. The question to be determined was, therefore, whether these claims were valid.

Judge Geiger's decision is to the effect that these claims are not valid, because they do not cover processes or apparatus or products which were new and original with Dr. Taggart. They had all been developed, used, and given to the profession long before Dr. Taggart obtained his patents.

Dr. Taggart's attorneys have announced that these thirteen test cases will be taken to the Court of Appeals, which is the court of last resort in patent cases.

DENTAL COLLEGE COMMENCEMENTS

Cincinnati College of Dental Surgery.

THE commencement exercises of the Cincinnati College of Dental Surgery were held at the Business Men's Club, Cincinnati, Ohio, May 29, 1918.

An address was made by Dr. G. S. Junkerman, dean.

The degree of Doctor of Dental Surgery was conferred by E. W. Wilkinson, president of the board of trustees, upon the following graduates:

| | | | |
|--------------------|--------------------|--------------------|------------------------|
| Carl E. Becker | James C. Johnson | Jacob E. Levin | Elmer C. Threlkeld |
| Frank A. Coburn | William R. Knight | Charles T. Meiring | David D. Tomb |
| Alfred Friedman | Albert S. deLatour | Leon Reisenfeld | George W. Watkins, Jr. |
| Clarence D. Hughes | J. Kalman Leon | Earl C. Smith | |

Ohio State University, College of Dentistry.

At the annual commencement exercises of the College of Dentistry of Ohio State University, held in Columbus, Ohio, May 28, 1918, the degree of Doctor of Dental Surgery was conferred on the following graduates:

| | | | |
|-----------------------|--------------------------|----------------------|----------------------|
| Thomas F. Auld | Clarence S. Delashmutt | Nelson S. Hoover | Chester E. Rasor |
| Harold W. Babington | Elijah D. Douglass | Fred F. Jones | Thomas W. Ream |
| Walter D. Barcroft | Harry H. Douglass | Morton H. Jones | Harry E. Sarchet |
| Charles E. Beatty | John W. Dunbar | Leroy H. Kauffman | Earl M. Sheehan |
| Robert J. Bennett | James E. Dunn | Albert N. Kishler | Alice M. Smith |
| Paul D. Black | Arthur M. Elam | Myron W. King | Jasper W. Tall |
| Dean H. Booth | Botner F. Elam | Robert A. Lush | Richard M. Titus |
| Wm. B. Braumiller | Hubert B. Eyman | Bruce A. Mayer | Eurat D. Vosper |
| Herbert F. Brown | Oscar J. Fillinger | Robert P. Merrill | Homer C. Wagner |
| Edward P. Buddenhagen | Austin T. Fisher | Davison B. Moore | Everett L. Watkins |
| Claude M. Campbell | Phillip A. Floyd | Alva C. Myers | Chester E. Wetherill |
| Leo M. Carr | Ira L. Fulk | Ernest R. Myers | Russell H. Wetzel |
| Joseph F. Carroll | Harold W. Hart | Joseph C. Nageleisen | Leonard O. Wheeler |
| Adonis G. Cashbaugh | Arthur A. Hartupee | Victor Park | William D. Williams |
| Franz C. L. Claypool | Robert W. Heibertshausen | Jean M. Putnam | Harold G. Wolfe |
| Ralph B. Clugh | | | |

McGill University, Department of Dentistry.

At the annual convocation of the Department of Dentistry of McGill University, held in Montreal, Can., the degree of Doctor of Dental Surgery was conferred on the following graduates:

| | | | |
|----------------------|----------|--------------------|----------|
| B. Gold | Montreal | J. W. Rooney | Quebec |
| C. N. P. Moore | Quebec | Myer Solomon | Montreal |
| V. S. Primrose | Maryland | | |

Georgetown University, Dental Department.

At the annual commencement exercises of the Dental Department of Georgetown University, held in Washington, D. C., the degree of Doctor of Dental Surgery was conferred on the following graduates:

| | | | |
|-------------------|-------------------|-------------------|-------------------|
| Charles Basseches | Harold V. Garrity | Francis M. Murray | Nevel K. Rodgers |
| John E. Black | Stephen F. Hardy | Joseph Norman | Edwin W. Schultze |
| David D. Bowman | Patrick Kelleher | Thomas W. Power | Charles L. Smith |
| Harold M. Britton | Joseph J. Klauser | Albert A. Reilly | Doran S. Thorn |
| Richard J. Curran | Charles Longcor | George L. Reilly | Arthur L. Vickery |
| Andrew F. Gaffney | Joseph C. Munster | Joseph G. Reilly | Benjamin Yarowsky |

North Pacific College.

THE annual commencement exercises of North Pacific College were held on Wednesday, May 29, 1918, in Portland, Ore.

Addresses were delivered by Herbert C. Miller, M.D., D.D.S., Dr. Joshua Stansfield, and Calvin S. White, M.D., Major M.R.C.

The degree of Doctor of Dental Medicine was conferred by the president of the college, on the following graduates:

| | | | |
|--------------------------|--------------------|-----------------------|----------------------|
| Henry F. Adler | Oliver G. Garrett | George S. McCord | Eugene Rollefson |
| Korenori Anan | Arthur F. Grabbert | David A. MacEachern | Arthur N. Russell |
| Cedric C. Anderson | Edward E. Gray | Joseph F. Maguire | William A. Rutledge |
| Oswell A. Anderson | Fred E. Gulick | Ralph W. Maris | Harvey A. Schneider |
| Thomas C. Bailey | Ernest H. Hall | Carl L. Marquardt | Norman H. Scott |
| William S. Balcom | Ralph M. Hamstrom | George W. Marshall | Andy W. Sears |
| Arthur F. Balkema | James E. Harding | Lloyd M. Masemore | Harry Semler |
| Alfred H. Bayne | Fisher L. Hauer | Wagner H. Mast | Harry Sirginson |
| Joseph Bell | James G. Hazlett | Leroy J. Maurer | Frank E. Sprague |
| Norman Bouchet | Julius H. Held | Clarence B. Messamore | Lloyd R. Springer |
| John C. Breckenridge | Claude E. Hicks | Carl E. Miller | William M. Stern |
| Clarence L. Brown | Robert E. Hill | James D. Neidich | Charles L. Stolte |
| John D. Butler | Rowland W. Hill | William S. Newitt | Frank D. Sullivan |
| Douglas A. Casselman | Henry C. Houck | Angus C. Nicholson | Clayton D. Sumner |
| Kenneth B. Casselman | Laron D. Hyde | Paul McK. Noel | Yanosuke Takeda |
| Roy E. Cate | Albert F. Ihinger | Urban P. O'Connor | Leonard F. Tepoorten |
| James M. Chilson | Walter L. Iles | John C. Page | Laurence E. Thornton |
| Harold A. Christoffersen | Clarence H. Irwin | Thomas W. Parker | Joseph M. Timlin |
| Clifford O. Dennis | Lewis J. Keliher | Chauncey C. Peck | Clinton B. Titus |
| Raymond E. Dickinson | Alpha M. Koester | Bennie H. Pedersen | Leif Underdahl |
| Fred J. Dingle | Charles A. Lamkin | Guy M. Perham | Eber H. Utter |
| Thomas S. Dulin, Jr. | Otto R. Leavell | Walter H. Pickering | Arthur C. Wagner |
| Anders Ejde | William E. Lebow | Gerald L. Plant | James T. Walls, Jr. |
| Frederick M. Elworthy | John R. Lighty | Nate S. Reingold | Howard M. Wheeler |
| Otis N. Farley | Carl R. Lofgren | William W. Robbins | Jerome H. Whisler |
| Irvin V. Franckenberg | Forrest A. Lowe | Oscar W. Rogers | J. Handley Williams |
| Abram G. Friedline | John J. McCarthy | | |

New York College of Dentistry.

THE fifty-second annual commencement exercises of the New York College of Dentistry were held in Carnegie Hall, New York, N. Y., on Monday, June 10, 1918.

An address to the graduates was delivered by Alexander W. Thornton, L.D.S., D.D.S., D.Sc.

The degree of Doctor of Dental Surgery was conferred by David Webster, M.D., vice-president of the board of trustees and directors, on the following graduates:

| | | | |
|---------------------|-------------|-------------------------|------------|
| Thomas J. Agnew | New Jersey | Victor A. Granelli | New Jersey |
| Herman R. Ahlers | New York | Joseph C. Green | New York |
| Louis D. Amsterdam | New York | Samuel Greenberg | New York |
| Wendell M. Arnold | New York | Solomon Greenberg | New York |
| Nehemiah Aronson | New York | Benjamin S. Greenberger | New York |
| Julius Baldwin | New York | Abraham Greenky | New York |
| Maurice S. Barshad | New York | Albert C. Grimm | New Jersey |
| Morris B. Bernfeld | New York | Benjamin Gross | New York |
| Harry L. Bernstein | New York | Charles Grossman | New York |
| John J. Bider | New Jersey | Stephen F. Guntner | New York |
| Samuel H. Bolotsky | New York | Benjamin B. Haas | New York |
| Bernard Bor | New York | Charles Haimowitz | New York |
| Abraham Brand | New York | Arthur Harrison | New Jersey |
| Henry Braunstein | New York | Charles Hattauer | New York |
| Benjamin Breger | New York | Abraham J. Hertz | New York |
| Milton M. Bronstein | New York | Ellis Hoffman | New York |
| Isidor Brooks | New York | Everett L. Hoffmire | New Jersey |
| Milton Bruder | New York | Howard C. Hoxsie | New York |
| John F. Burke, Jr. | New Jersey | Sidney S. Jedel | New Jersey |
| Harry Cherry | New York | Edward A. Jurek | New York |

| Harry B. Silver | Connecticut | Joseph Zuckerman | New York |

Loyola University, School of Dentistry.

At the commencement exercises of the School of Dentistry of Loyola University, held in New Orleans, La., the degree of Doctor of Dental Surgery was conferred on the following graduates:

| | | | |
|----------------------|------------------|---------------------|------------------|
| George L. Agin | Alfred B. Browne | J. Nicolas Martinez | Clemens V. Rault |
| Henry L. Bowman | John S. Faulk | Bernard J. Prejean | George H. White |
| Laurent T. Broussard | Mary J. Howard | | |

Royal College of Dental Surgeons.

At the regular 1918 commencement exercises of the Royal College of Dental Surgeons of Ontario, held in Toronto, the degree of Licentiate of Dental Surgery was conferred on the following graduates:

| | | | |
|-------------------|---------------------|-------------------|-------------------|
| Francis H. Barry | Hugh K. Henderson | Alex. McCuaig | Theobald Regnier |
| Archibald W. Boyd | Elford V. Humphreys | Edmund S. McGowan | Bernard Schaffer |

| F. C. Harwood | G. H. Jones | Moore F. McRae | E. C. Young |

College of Jersey City, Department of Dentistry.

At the annual commencement exercises of the Department of Dentistry of the College of Jersey City, the degree of Doctor of Dental Surgery was conferred on the following graduates:

Joseph Bleich

Meyer Millekofsky

Lincoln Dental College.

THE annual commencement exercises of Lincoln Dental College were held in Lincoln, Nebr., on June 1, 1918.

An address was delivered by Rev. L. D. Young.

The degree of Doctor of Dental Surgery was conferred by the dean, Dr. Clyde Davis, on the following graduates:

Burnham B. Ames
Earl C. Andrew
John G. Aukes
Leonard S. Biddlecom
Frederick L. Blessing
August E. H. Blomenkamp
Lawrence D. Bromfield
Hubert A. Capek

Don T. Clark
Harry E. Colbert
Alfred E. Curley
Perry L. Evans
Clarence W. Granger
Donald S. Hinman
Harold A. Howard
Arvid Karlson

Frank H. Miller
Richard D. Minnick
Clyde A. Nelson
George D. Odiorne
Harold F. Parish
Harold G. Patterson
David J. Pope
Irving W. Pratt

Jerome M. Pucelik
William E. Smith
Elmer E. Swanbom
Fred G. Thomas
Hugh C. Thomas
Eldo G. Tucker
Frank A. Wilson
Ray E. Witham

Indiana Dental College.

THE annual commencement exercises of Indiana Dental College were held on Tuesday, June 11, 1918, in Indianapolis, Ind.

An address was delivered by Prof. Oscar H. Williams.

The degree of Doctor of Dental Surgery was conferred by Dr. John N. Hurty, president of the board of trustees, on the following graduates:

Oral D. Adams
Lex C. Arnett
Charles E. Arnold
Merrill R. Baker
Harry S. Banks
Alvin E. Barkes
Forrest R. Bell
Frank M. Belt
Marvin T. Botkin
Frank W. Boyd
Runo G. Brodeen
Raul V. Brown
Harry E. Bruner
Rodolfo A. Campani
Lester M. Choate
Arthur E. Christerson
Clarence F. Coleman
Albert R. Collins
George M. Cropp
Matthew S. Cnff
Charles S. Davis
Fenton B. Davison

Ross L. Davison
Enoch H. Derriek
Carson W. Dietrich
E. Millard Dill
Harold C. Downing
Edgar F. Duvall
Arthur W. Edman
Willis B. Eggleston
John S. Eilar
John A. Elliott
Harry Epstein
Noble R. Fox
Edgar A. Frantz
Hugh J. Gallagher
Perry C. Garman
W. Orville Godwin
John B. Gordon
Cameron N. Griffith
Robert L. Guedel
Earl E. Hoffa
Frank L. Hubbard

Frank C. Hughes
Don F. Irvin
Von L. Kennedy
Karl P. Kretch
Neal M. Loomis
Earl L. McKee
Robert McKee
John E. Martin
Cullen B. Meckel
Elmer H. Miller
Carl F. Morganthaler
Leo R. Newberger
Ralph J. Overstreet
George L. Oyler
John P. Parr
Claude E. Pierce
Joseph E. Pulley
Alexander D. Pow, Jr.
Samuel J. Purviance
Lynn G. Reed
Fred W. Richards

S. Paul Richards
Wade D. Rogers
Stark O. Sanders
Harry A. Schiess
Harry M. Schneider
Russell F. Shafer
Alphonso P. Shipman
Thomas C. Smiley
Stewart B. Smith
James C. Stewart
Ellis Y. Tagawa
Howard Thomas
Jesse V. Towe
Ralph S. Turner
Clinton P. Walker
Louie E. Wampler
Barney J. Warezak
James C. Weatherholt
Emil L. Welsh
Lee E. Wherry
Douglas H. White

Washington University, Dental Department.

THE fifty-seventh commencement exercises of Washington University Dental Department were held on Thursday, June 13, 1918, in St. Louis, Mo.

An address was delivered by Edmund Janes James, Ph.D., LL.D., president of the University of Illinois.

The degree of Doctor of Dental Surgery was conferred by Chancellor Frederic Aldin Hall, LL.D., on the following graduates:

| | | | |
|------------------------|-----------------------|-------------------|-----------------------|
| John M. Beard | William H. Freshour | James D. Nelson | Lawrence A. Snively |
| Carl J. Beinker | Bertram E. Gilster | Harry Oksner | Larkin E. Stark |
| Frank D. E. Benway | Moses Glassman | Roy C. Parkhill | Edward L. Stroh |
| James L. Bowman | James E. Harding | Lyle D. Perry | William Stroh |
| Francis J. Brandenburg | George H. Herbert | Evan W. Petty | Robert J. Throgmorton |
| George H. Bredall | Walter H. Heseman | Lizzie R. Powell | Seth C. Thomas |
| Harold H. Brummall | Thomas R. Hollinshead | Calvin A. Reibert | Thurlo T. Weir |
| Walter L. Buck | Irvin J. Kehr | Elmer Reising | Walter W. Wieman |
| Grover C. Clay | Wycliffe E. Kling | Alvin V. Sanders | Samuel F. Wilmesher |

The Thomas W. Evans Museum and Dental Institute School of Dentistry University of Pennsylvania.

At the annual commencement exercises of the Thomas W. Evans Museum and Dental Institute School of Dentistry University of Pennsylvania, held Wednesday, June 19, 1918, at the Metropolitan Opera House, Philadelphia, Pa., the degree of Doctor of Dental Surgery was conferred by Edgar F. Smith, Chem.D., Sc.D., L.H.D., provost, upon the following candidates:

| | |
|-------------------------------|---------------------|
| Stuart G. Abel | Pennsylvania |
| David A. Alberstadt | Pennsylvania |
| Earl H. Albert | Pennsylvania |
| Garrett Albrecht | Pennsylvania |
| Luis C. Aleman | Panama |
| Earl J. Allen | New York |
| Harold E. Anderson | New Jersey |
| Juan B. Arias | Panama |
| Harvey M. Aungst | Pennsylvania |
| Harold C. Bailey | Pennsylvania |
| Bella B. Barash | New York |
| Alexander R. Bartsch | New Jersey |
| Joseph C. Bauer | Connecticut |
| John A. Bauerle | Chile |
| Leonard R. Becker | Pennsylvania |
| Walter E. Bender | New York |
| Abbott Berger | New York |
| Walter J. Bernhardt | New York |
| John W. Berryman | New York |
| Cayetano Bethencourt | Canary Island |
| Leon W. Bivins | Pennsylvania |
| Ralph W. Boone | Maine |
| William R. Borneman | Pennsylvania |
| Clyde S. Bouton | New York |
| Ernest H. Braem | New York |
| Samuel Bragman | New York |
| Edward Brailove | New Jersey |
| Eulogius J. Brennan | Pennsylvania |
| Harry N. Brenner | Pennsylvania |
| Finn J. Brønner | Norway |
| James E. Brown | New Jersey |
| Roy H. Brown | New Jersey |
| Russell C. Brown | New Jersey |
| Vincent T. Buggy | Pennsylvania |
| Louis A. Candela | New York |
| Samuel M. Carter, Jr. | Pennsylvania |
| Abraham de Castro | Panama |
| Lawrence D. Christmas | Pennsylvania |
| Harold O. Clappier | Pennsylvania |
| Robert Clayton | Pennsylvania |
| Herbert E. Cohen | Pennsylvania |
| John T. Cologne | Tennessee |
| Harold D. Colt | Pennsylvania |
| Willard R. Conklin | New Jersey |
| George W. Connell, Jr. | New York |
| Charles S. Conover | New Jersey |
| Morris L. Cooper | Tennessee |
| Everett E. H. Covert | New Jersey |
| Alberto J. Cuadra | Central America |
| Walter H. Danforth | Vermont |
| George C. Davis | Pennsylvania |
| William H. Dean | Pennsylvania |
| Seymour C. Deber | New Jersey |
| Marshall G. Derk | Pennsylvania |
| Rafael Deshon | Central America |
| Joseph W. Dillon | New Jersey |
| Lazarus A. Dughi | Pennsylvania |
| Ralph G. Eveland | New York |
| Gregorio Fabiani | Italy |
| Henry W. Farrell | New York |
| Henry A. Finestone | Pennsylvania |
| Francis J. Fitzpatrick | Pennsylvania |
| Chester D. Forkel | New York |
| Herbert P. Frank | New York |
| John W. Gabler | New York |
| Carl C. Gage | New York |
| David J. Ganey | Pennsylvania |
| Julian I. Gifford | New York |
| Julius I. Gifford | New York |
| Holmes R. Gillhuly | New Jersey |
| Charles A. Gilmartin | Connecticut |
| Mareo Giovagnoli | Italy |
| James B. Gosnell | Canada |
| Harry K. Gurnsey | Utah |
| John J. Haas | New Jersey |
| Warren L. Hafely | New York |
| William R. Haller | New York |
| Wilbur T. Harkrader | New Jersey |
| Arthur W. Harrington | Massachusetts |
| Whitton R. Hatfield | New York |
| Robert W. Haycock, Jr. | New Jersey |
| Ollington C. Hayes | New Jersey |
| Robert M. Heilbrun | New York |
| Robert A. Henke | New York |
| Elam M. Hitchner | New Jersey |
| Charles H. Hodgkins, Jr. | Maine |
| Leslie L. Hoke | New York |
| Francis G. Hollar | British West Indies |
| Elmer P. Hollingshead | New Jersey |
| Ralph H. Honsberger | Pennsylvania |
| Frank K. Horner | New Jersey |
| Ashley E. Howes | New York |
| Earle B. Hoyt | New Jersey |
| Rudolph Hyman | New Jersey |
| Meredith M. Jack | Pennsylvania |
| Reginald R. Jacobs | South America |
| Earl W. Jaynes | Pennsylvania |
| Thomas R. Jenkins | Pennsylvania |
| Wesley F. Jerauld | Maine |
| Jay P. Jeter | Pennsylvania |
| Ethan A. Johnson | New York |
| Lewis S. Johnson | Maine |
| Harold S. Jones | Pennsylvania |
| Irving Joseph | New York |
| Morris H. Jossem | New York |
| Harry L. Keel | North Carolina |
| Edward B. Keffer | Pennsylvania |
| Howard R. Kidd | Pennsylvania |
| Donald J. Klotz | Pennsylvania |
| George Kobre | New York |
| Samuel Konwiser | New Jersey |
| Frederick H. Kroll | Pennsylvania |

| | | | |
|-----------------------|----------------------|------------------------|-----------------|
| Clyde D. W. Kuich | Pennsylvania | Aubrey P. Sager | Pennsylvania |
| Thomas R. Lahey | New Jersey | Harry M. Sassaman | Pennsylvania |

Degree conferred (as of class of 1917) at University Council,
February 22, 1918:

Geo. A. Encherman

James J. McMillan

John Wm. Ross

Conferred January 16, 1918:

Carl Sorgenfrei

Laval University, School of Dental Surgery.

At the commencement exercises of the School of Dental Surgery of Laval University, held in Montreal, Can., the degree of Doctor of Dental Surgery was conferred on the following graduates:

| | | | | |
|-------------------|-----------------|------------------|--------------------|---------------|
| Theo. Archambault | Honoré David | Arm. Hay | A. W. Maitland | Palma Racicot |
| Eug. Audet | Gaston Demers | Arist. Lacasse | Eulide Malo | L. Ringuette |
| Emile Bourbon | Henri Desroches | Léon Leduc | Auguste Massicotte | Arm. Sarrazin |
| Ch. Campeau | Bruno Dugas | L. C. LeSage | J. A. Pinault | R. E. Trudeau |
| Antonio Chevrier | Ch. Duquette | Cyprian Lévesque | Horace Pinet | Emile Venne |
| Geo. Cinq-Mars | Aug. Graton | Robert MacKay | Ed. Plourde | E. Vinet |
| Z. A. Côté | | | | |

The degree of Bachelor of Dental Surgery was conferred on the following graduates:

| | | | | |
|--------------------|------------------|-----------------|-----------------|------------------|
| Ch. E. Beaulieu | Eulide Caza | Gustave Gouin | Edgar Larouche | Henri Provencher |
| Ludger Bissonnette | J. B. Dorval | Gratien Landry | J. B. Melançon | Geo. Pelletier |
| Moise Brassard | Clovis Denis | Antoine Loignon | Angelbert Milot | Rodolphe Philie |
| Jules Brière | Sam'l H. Feldman | Charles Larue | | |

St. Louis University, Dental Department.

THE annual commencement exercises of the Dental Department of St. Louis University were held in St. Louis, Mo., on June 3, 1918.

The commencement address was delivered by Hon. C. J. Smyth, Chief Justice, Court of Appeals, D.C.

The degree of Doctor of Dental Surgery was conferred on the following graduates:

| | | | |
|-----------------------|--------------|------------------------|--------------|
| Sanford H. Allen | Missouri | Murray Ipe | Indiana |
| Harry Baker | Illinois | Elmer A. Jasper | Missouri |
| Lee A. Bierk | Missouri | Mark C. Kerr | Pennsylvania |
| John A. Boudreau | Missouri | Alphonsus J. Lager | Missouri |
| John F. Brandt | Missouri | John H. McCutchen | Missouri |
| Hugo H. Buescher | Missouri | Paul L. Mallinekradt | Missouri |
| Joseph F. Buxton | Illinois | Leo K. Manning | Missouri |
| William Cain | Illinois | William E. Nolting | Illinois |
| James B. Cuthbertson | Illinois | Walter G. Oeh | Illinois |
| Victor Droste | Illinois | Alfred Perry | Missouri |
| Robert T. Eads | Missouri | Earl J. Poe | Illinois |
| Gus H. Eckert | Missouri | Walter K. Richardson | Missouri |
| Sylvan Eisenstein | Missouri | Frederick J. Robertson | Arkansas |
| John A. Evans | Ohio | A. E. Seymour | Illinois |
| Harry H. Fleischer | Missouri | Loyd Shimmis | Utah |
| George Franken | Ohio | Walter G. Siemers | Missouri |
| Henry C. Fulkerson | Illinois | John C. Skaer | Illinois |
| Paul H. Gattermeir | Missouri | Howard S. Smith | Missouri |
| Francis P. Gleeson | Ohio | Leonard A. Smith | Arkansas |
| Otho A. Gorman | Illinois | Edward F. Stallman | Illinois |
| John J. Gormley | Missouri | Lou R. Starling | Missouri |
| Chester D. Grimes | Pennsylvania | John G. Stephens | Missouri |
| Claude E. Grizzell | Illinois | Zera L. Stokely | Missouri |
| Ambrose B. Harrington | New York | Zeph W. Street | Missouri |
| Francis M. Hayden | Missouri | Benjamin C. Thompson | Missouri |
| George B. Herndon | Missouri | Everett Travelstead | Illinois |
| Henry Heyenga | Illinois | William F. Truetzel | Missouri |
| Claude D. Holder | Missouri | Ferdinand J. Vogelsang | Illinois |
| Garnett G. Hopkins | Missouri | Edwin R. Wagner | Illinois |
| Arden Hunt | Utah | Frank J. Weicht | Indiana |
| Henry J. Huschle | Illinois | George W. Williams | Missouri |

Western Dental College.

At the annual commencement exercises of Western Dental College, held in Kansas City, Mo., the degree of Doctor of Dental Surgery was conferred on the following graduates:

| | | | | |
|----------------|----------------|---------------|---------------------|-----------------|
| R. H. Ahrens | J. H. Dillon | F. A. Holmes | H. Neiswanger | C. Sheldon |
| E. K. Arnold | W. J. Doran | P. C. Hopkins | L. J. Nipher | Ben Simlevick |
| Glen Ault | W. F. Drew | H. E. Johnson | D. A. Pedroja | F. L. Soper |
| W. E. Baker | F. B. Farr | H. B. Johnson | H. A. Potter | C. Stigdon |
| J. D. Bast | W. E. Foley | J. A. Jones | L. J. Reid | R. C. Sweeney |
| G. G. Brown | F. A. Foyle | V. Jones | W. P. Ringo | Ed. H. Thompson |
| J. E. Brown | J. H. Gilman | J. T. Keeling | L. O. Rippey | G. T. Wallace |
| C. N. Bucher | F. A. Greene | G. F. Kling | Mrs. C. B. Robinson | J. Wilhite |
| L. C. Cox | Miss J. Harris | O. J. Koepke | L. L. Sauder | R. Wright |

ARMY AND NAVY DENTAL NEWS

Enlistment in Medical Enlisted Reserve Corps

OF

Students in Well-recognized Dental Schools.

THE following circular for the information of dental students has been issued from the Surgeon-general's office, Washington, D. C.:

1. The applicant secures from his local board a certificate showing that he is not in the current quota.

2. The applicant makes out an application for permission to enlist following in every particular Form ASGS.

3. The certificate of the local board and the application for permission to enlist are given to the dean.

4. The dean attaches his affidavit (following one of the Forms DVS) and makes a record of having issued the affidavit.

5. The dean sends the application, the certificate of the local board, and the affidavit by mail to the Surgeon-general of the Army (*Personnel* division, Section on Medical Education, Washington, D. C.). (This *entire* address should appear on envelope to avoid delay.)

6. If approved, the Surgeon-general's office issues a permit and sends it to the dean.

7. The dean records receipt of this permit on his register of affidavits issued, and gives permit to the applicant.

8. The applicant makes out an application to enlist following Form ARO, and presents this with the permit to a recruiting officer.

9. The recruiting officer receives the man for enlistment and either gives him a physical examination or sends him to a medical officer of the army for physical examination.

(a) If the applicant is rejected on account of minor defects only, the examining officer will, upon request, forward a copy of the physical examination to the Surgeon-general for consideration of waiver of these defects.

10. After enlistment is completed, the applicant should secure a certificate of enlistment from a *medical officer* of the army. If the recruiting officer is not a medical officer, he should be asked to furnish a statement of the fact of enlistment, which may be presented to the medical officer who made the

physical examination as a basis for this certificate.

11. The applicant presents this certificate of enlistment to his local board as a basis for deferred classification.

12. The applicant notifies the officer of his school who made the affidavit, of the date and place of enlistment, and this is entered by the officer on the register of affidavits.

A careful following of these steps will expedite enlistment and save much time and useless correspondence. The Surgeon-general's office cannot furnish supplies of this circular or of forms of application and affidavit, but there is no objection to the school issuing copies to men who are now or soon will become eligible for enlistment.

By direction of the Surgeon-general:

May 20, 1918. F. C. WAITE, *Captain,*
Sanitary Corps, N. A.

Recruiting of Student Nurses for the Army.

A NATION-WIDE campaign to recruit 25,000 student nurses, both for the Army School of Nursing and for all accredited training-schools connected with civilian hospitals is to be launched on July 29th.

It will be conducted under the direction of the Woman's Committee of the Council of National Defense upon the request of the Committee on Nursing, General Medical Board. It will be strongly supported by the co-operation of the Surgeon-general's office, the American Red Cross, and of the General Medical Board and State Councils Section of the Council.

It is designed to be a direct appeal from lay women to the young womanhood of America to enter upon a course of nurse training. The appeal will be made on the basis that every day of a student nurse's training represents a double patriotic service, in that while she is preparing for military duty later,

she releases a graduate for military duty now and herself cares for the civilian population.

The Committee on Nursing and the Woman's Committee join me in urging the medical profession through our state and local committees to encourage the families of their patrons to respond to this call; and also to lend their hearty co-operation during the recruiting days. It is especially desirable to use this opportunity to point out the fact that the maintenance of local hospitals and the training schools connected with them is an imperative community obligation.

FRANKLIN MARTIN, *Ch'man Med. Board,
Council of National Defense.*

WASHINGTON, D. C., July 3, 1918.

Enough Army Dentists.

THE dental requirements of an army of more than 5,000,000 men can now be met by the present force of the dental corps of the American army. Examinations for dental officers have been closed, and no further additions will be made to the corps for at least six months. At the time the United States declared a state of war to exist between this country and Germany the total number of dental officers was 58. The present force numbers 5810. Commissions were offered to 5467 dentists in all parts of the country, and all but 271 were accepted, a percentage of 95.1. A school for dental instruction has been started at Fort Oglethorpe, Ga. Eighty-five dental officers are assigned each month to take the two months' course. The first month is given over to 180 hours of general military instruction and training, and the second to 70 hours' special military training and 100 hours devoted to professional subjects that have a definite relation to general practice of dentistry as it should be conducted in the army. Special dental infirmaries have been established in the camps and cantonments in this country, to which every newly inducted soldier is sent for examination shortly after arrival in the camp. In those cases where men need attention it is given. The average number of tooth fillings is from 225,000 to 250,000 a month. This figure does not include the examinations, treatments, extraction, or crown, bridge, and plate work. The practice followed in the camps is to first give treatment to those cases that require immediate attention. Special attention is paid to determining the number of chronic infections associated with teeth. It has been found that a number of diseases incapacitating men for military service are traceable to chronic infections about the teeth. Dental inspectors are constantly visiting camps and cantonments to inspect work done by the camp

dentists in order to determine if the dental officers are competent, are correctly assigned, and to report on the general efficiency of the units. The same thorough care that is given to the men in this country is also given to the men in France. With each base, general, or evacuation hospital there is attached a specialist in plastic surgery to correct deformities of face and jaws. Dental surgeons who have been specially trained in this class of work are also assigned to such hospitals. —*Army and Navy Register.*

"The Army's Teeth."

BRITISH ARMY.

MR. J. P. LEEMING writes from Parkside, Great Clowes st., Higher Broughton: "As dental surgeon to seven Red Cross hospitals, I can testify to the state of the army's teeth. Many of the men have been invalidated home with chronic stomach trouble due to bad teeth; and others who are wounded have not the same rapidity of recovery when all their food has to pass through a mouth full of septic teeth. From data which I have carefully taken I find that most of these men had bad teeth when they entered the army and were sent out to the front without dental treatment. All the qualified dentists serving in the army as combatants should be used as dentists, where they could render fit thousands of men otherwise unfit for active service. The dentists have not been slow in offering their services. I was informed in 1915 that there was a waiting list of over 800 dentists who had offered their services to the War Office. This list will now be much longer, and the majority are still waiting." —*British Journal of Dental Science.*

The American Army in France.

IN the course of a remarkably interesting review which Mr. Edward Marshall, a correspondent of the *Observer*, had with General Pershing, the general made the following comments upon marginal gingivitis: "The general physical health is of the best. 'Trench mouth' is not uncommon among the British Tommies, and our men have begun to know a little of it, but they never will be generally victims of it as the British and French were for a time, and even are today, because their teeth have for the most part been better cared for than those of their allies." This is a remarkable tribute to the high importance which the commander of the American army attaches to the preventive power of dental treatment in adding to the number of combatants borne upon the active roll of the army. —*British Dental Journal.*

Naval Dental Corps.

THE provision for the Naval Dental Corps as finally agreed to by the Senate and House limits the rank of dental officers to that of lieutenant-commander instead of commander, as provided in the Senate amendment, and strikes out the provision requiring confirmation of appointments. While the rank is limited to lieutenant-commander, provision is made for pay and allowances to the rank of captain and commander. This was done to prevent a conflict in authority. This meets the wishes of the Secretary of the Navy, who made the following statement concerning the proposed legislation:

"The appropriation bill, as it now stands, provides roughly for 13 dentists with the rank of commander. The department believes that dental officers should not be commissioned in a grade above that of dental surgeons with the rank of lieutenant-commander, for the reason that it now has no billets, nor can it foresee any billets in the future, in which a dentist of such high rank can be employed, certainly not to the number of 13. It is the policy of the department to give increase in rank only when such is necessary to facilitate command and administration for the purposes of war or preparation for war, and never as a matter of personal reward. Its recommendations to Congress in the matter of rank have been on this ground solely. It, however, believes that dental surgeons of long service should be permitted to have an increase of pay up to and including that given to a captain in the navy."—*Army and Navy Register*.

[SEE also page 733, "Naval Appropriation Bill—Provision for the Naval Dental Corps." under Dental Legislation.—ED.]

Examination for Naval Dentists.

EXAMINATIONS were begun this week to fill prospective vacancies in the Naval Dental Reserve corps, due to the increases allowed in the current appropriation bill. These examinations were held in Washington, New York, Philadelphia, Norfolk, Great Lakes, and San Francisco. The complement of the naval dental corps is 1:1000 of the total *personnel*. Over 300 are allowed at present, and when the Navy bill passes, over 100 additional vacancies will be created. The present examinations are for the purpose of making appointments in the reserve only, the minimum age limit for which is twenty-one years. An examination for the regular service was held some time in October.—*Army and Navy Register*.

Vincent's Angina Among the Troops in France.

DURING the last two years there has been a gradual and marked increase in the number of cases of Vincent's angina among the troops in France, both British and French. In time of peace this disease forms about 2 or 3 per cent. of all cases of throat complaints among the French army (recent statistics). Recent statistics from a British military hospital in France show the proportion to be as high as 23 per cent. The following notes are based on a number of cases which have come under my observation:

SYMPTOMS.

The disease is characterized by the formation of ulcers on the buccal and pharyngeal mucous membrane, either superficial or deep, covered by a pseudo-membrane—the most common site is the tonsil. The organism is one normally present in the mouth of healthy individuals, but seems to favor irritated conditions of the mucous membrane. Vincent himself considers excessive smoking one of the chief predisposing factors, as also the presence of decaying organic matter, and any irritating fumes, such as those given off by exploding shells. It is a disease prevalent among students working in the dissecting-room, and in hospitals generally, and among nurses. The onset is sudden, and may be preceded by a few days' malaise. The temperature is raised for the first day or two, and may be high, the membrane often not commencing to form for twenty-four to forty-eight hours after the commencement of the fever. The membrane is rapidly formed, is thick and abundant, and appears, as a rule, on one tonsil at first. After the first two days the temperature may fall to normal, and remain normal, or there may be an irregular slight pyrexia throughout. This more often occurs in the more severe type with complications, such as marked adenitis or albuminuria, etc. The membrane is yellowish white and abundant, it is adherent, and leaves a raw bleeding surface on removal. Although the tonsil is generally the part affected, the ulcer may be found only on the anterior or posterior pillar of the fauces, or the uvula alone, or the soft palate alone. It may commence on the tonsil, and spread to the uvula, pharyngeal wall, or soft palate, causing considerable destruction of tissue. The breath has an unpleasant odor, worse than in the case of diphtheria. As a rule, if thoroughly treated, the membrane disappears in a few days. In some cases, however, some days or as much as a fortnight after recovery, there

is a further rise of temperature, and commencing ulceration of the other tonsil. A chronic or severe form is sometimes seen, persisting for some weeks, and in these cases complications arise, and may be serious. Some cases of death have occurred in French hospitals in which the primary cause was Vincent's angina.

ETIOLOGY.

Microscopically, two varieties of organisms are found, the bacillus fusiformis and Vincent's spirochete. Two forms of Vincent's angina are met with—(1) the pseudo-membranous, resembling diphtheria in appearance, and (2) the ulcerative form. In the first we find abundant bacilli mixed with cocci; and in the second, associated with the bacillus, a Gram-negative mobile flagellated spirillum. A coexisting streptococcal infection is not uncommon, and may give rise to serious complications. The Ziehl-Neelsen method is all that is required, though the silver method demonstrates the spirochete more clearly. Injected into animals the organisms are non-pathogenic. Injection of impure cultures causes abscesses in which the spirochete is abundant. Letulle states that in every case of ulceration in the mouth, whether syphilitic, tuberculous, or cancerous, large numbers of *B. fusiformis* and spirilla are to be found.

COMPLICATIONS.

The complications which may occur are adenitis of the cervical glands in nearly every case, and often very painful.—CAPT. R. J. C. BOUTY, R.A.M.C.

—*British Medical Journal.*

Promotions.

Dental Reserve Corps.

THE following appointments (promotions) are announced (June 15th):

To be CAPTAINS: 1st Lieuts. Louis G. Prendergast, Donald M. Gallie, Jr., and Conrad E. Mortensen.

Announced June 22d:

To be MAJOR: Capt. Richard C. Kiebler.

Announced July 6th:

To be CAPTAINS: 1st Lieuts. Howard A. Reid, Fred L. McAninch, Arthur H. Nobbs, Henry O. Lineberger, Carlton B. Leighton, Walter E. Miller, Pope L. Marshall, Francis E. Derham, Solomon J. Z. Gantz, Henry H. Braxtan, Frank H. Cushman, Albert B. Crutcher, Carl M. Holland, Emory O. West, Fielding M. Wilhite, John B. Williams, Robert M. Schell, Thomas H. Tye. George

K. Patterson, Courtney J. Murphy, Alexander W. McClean, Nealie E. Ross, Robert A. Adkins, James H. Johnson, Matthew A. Boykin, Frampton W. Farmer, John H. Davis, Edward M. Atkinson, Harry B. Laird, Neal D. Williams, Wm. D. Rush, Elliott H. Rowland, Walter E. Lowrie, George G. Starke, Homer T. Kemper, John L. Remsen, Harvey B. Haselton, Max F. Gruber, Fred A. Beaty, James C. Campbell and Clarence A. Flanagan.

Assignments.

Army Dental Corps.

Week ending June 15th.

Maj. James G. Morningstar from present duties at Camp Bowie, Tex., to Camp Gordon, Ga., for duty as camp dental surgeon.

Maj. William Mann from present duties at Camp Zachary Taylor, Ky., to duty as camp dental surgeon.

Week ending June 22d.

Col. Franklin F. Wing from present duties at headquarters, Western department, and to duty as Western department dental surgeon.

Maj. Bruce H. Roberts from duty at Columbus Barracks, Fort Sam Houston, for duty with evacuation hospital 17.

1st Lieut. Roy C. Starr from duty at Camp Dix, N. J., to Deming, N. M., Camp Cody, for duty.

1st Lieut. Earl T. Dickman honorably discharged.

Week ending July 6th.

Maj. Bruce H. Roberts from duties with base hospital 2, Fort Bliss, to Fort Sam Houston for duty with evacuation hospital 17.

1st Lieut. Wm. J. R. Akeroyd from duties at Camp Zachary Taylor, Ky., to duty with evacuation hospital 18, that camp.

1st Lieut. Samuel J. Lewis from duties at Camp Meade, Md., to Alexandria, La., Camp Beauregard, for duty with base hospital 102.

Dental Reserve Corps.

Week ending June 15th.

Maj. Grove W. Dunham at Camp Custer, Mich., to duty as acting division dental surgeon.

Week ending June 22d.

Maj. Joseph A. Boarts to Columbia, S. C., Camp Jackson, for duty with evacuation hospital 14.

Maj. John McD. Eveleth to Camp Greene, N. C., for duty with base hospital 54.

Week ending June 29th.

Maj. John Voss to Rockford, Ill., Camp Grant, for duty with base hospital 58.

Preparedness League of American Dentists.

ORGANIZED UNDER THE AUSPICES OF THE N. D. A.

THE DENTAL COMMITTEE OF THE GENERAL MEDICAL BOARD, WHICH IS THE AGENCY FOR THE MEDICAL AND DENTAL PREPAREDNESS IN THIS WAR EMERGENCY, HAS MADE IT POSSIBLE FOR EVERY DENTIST IN THE UNITED STATES TO ASSIST IN THE WORK, UNDER THE SUPERVISION OF THE PREPAREDNESS LEAGUE OF AMERICAN DENTISTS.
HEADQUARTERS AT 50 EAST 42D ST., NEW YORK, N. Y.

Circular from Director-general Charles F. Ash,

115 BROADWAY, NEW YORK, N. Y.

THERE are just two classes of people in this country—those who are helping to the limit of their ability to win the war, and those who are not.

If you are a patriotic citizen you have no business in the latter class.

We are in this war to a successful finish, no matter how long it may take: and the quicker and more effective our health is, the shorter will be the struggle.

We must stop at no sacrifice, personal or financial, that the emergency may require.

We must consider our time and our capacities to be subject to conscription by our Government.

Let us translate our patriotism into action. The Government needs your help.

Let us make a clear declaration that we will back our Government with everything needed to help rid the world of this German menace which has brought the war to our very doors by sinking ships in American waters.

Our best opportunity is by making more men dentally fit, and thereby showing our determination to hasten our participation on the scale necessary for victory.

Our profession is going on record.

There are about 48,000 dentists in the United States.

Of this number 16,000 have joined the Preparedness League and agreed to give at least *one hour each day* of free service, including materials, to help make our boys dentally fit.

What is the matter with the other 32,000? Are they any less patriotic? I believe not. A few of them are doing free dental service for our boys, but have not joined the League. The others? Well, we are partly to blame in not having made them see the need for their help.

The inclosed report* shows 419,000 free operations performed for the men of our Army, Navy, and Marine Corps, but principally for those registrants who have been certified in Class 1A for our National Army.

We have 3,000,000 men under arms, and have done for them only 419,000 operations. Don't you see we need your help?

The wonderful work being done by Provost-marshal-general Crowder and his corps of able assistants in securing an army worthy of taking its place by the side of our Allies, must be backed up by every member of our profession who is physically able to practice.

Every boy made dentally fit increases the efficiency of our National Army. Kipling says:

It ain't the guns nor armament nor funds that
they can pay,
But the close co-operation that makes them win
the day;
It ain't the individuals, nor the army as a whole,
But the everlastin' team-work of every bloomin'
soul!

If you want to join the army that stays at home to help make our boys fit to fight, sign the inclosed application blank and forward as directed. Do it now.

If you are already a member, give the application blank to one who is not, and see that he joins.

TO DENTISTS ON LOCAL BOARDS AND MEDICAL ADVISORY BOARDS:

Through the work done by the League, dentists were placed on every medical advisory board and a volunteer dentist on every

* [A later statistical report similar to that published in the DENTAL COSMOS for July, at page 651.—Ed.]

local board in the United States. These men are doing an immense service to their country.

To the men on the advisory boards, let me say that where registrants certified for Class 1A come into your hands who have less than the minimum dental requirements, you should get in touch with the dentist on the local board that sent such registrant. Mention the case by name and order number, and call attention to the regulations as found in the new Selective Service Regulations, form 75, pages 15 and 16, sections 47 to 52.

TO THE VOLUNTEER DENTISTS ON LOCAL BOARDS: Many registrants have been certified for Class 1A and sent to camp who have less than the minimum dental requirements—some, even, with full upper dentures. This causes injustice to the registrant, expense to the Government, and embarrassment to your board. It is your duty to secure a copy of the new Selective Service Regulations, form 75, from the clerk of your board, and familiarize yourself with the dental regulations, page 15. You should assist the medical member of your board where requested, by examining the mouth and teeth of all registrants.

Last, and not least: It is your duty to secure the name, address, and order number

of every registrant for Class 1A who desires free dental treatment, and immediately put them in touch with the Preparedness League of American Dentists, so that there will be ample time for them to receive dental attention before going to camp. Don't wait until the registrants are ordered for entrainment, but send them for dental treatment as soon as they are classified in Class 1A.

The dentists on local boards occupy the most important position in relation to the dental condition of our National Army. The kind of service rendered by you will largely determine the success or failure of our efforts.

If any volunteer dentist assigned to a local board has difficulty in securing recognition by his board, he should promptly report his case to the Preparedness League director for his state, who will see that the matter is promptly taken up by the Adjutant-general of the State.

The governors of the various states and their adjutants and medical aides have been giving us splendid co-operation, and stand ready to assist us in performing our patriotic duty.

Herewith is a copy of a letter which every member should read. [See following letter.]

CHAS. F. ASH, *Director-general.*

July 2, 1918.

(Inclosure.)

WAR DEPARTMENT: OFFICE OF THE PROVOST MARSHAL GENERAL,
WASHINGTON, June 8, 1918.

DR. J. W. BEACH, Pres. Preparedness League of American Dentists, Buffalo, N. Y.

Dear Sir,—This is to acknowledge your favor of June 4th, and to say that, together with inclosures, it has been carefully noted. This office very much appreciates the incalculable value of the work your League is doing, and the prompt and full co-operation of its officers with the Government.

In the course of the enormous work you are doing misunderstandings have necessarily arisen between dentists and the registrants for whom they were voluntarily working, but such misunderstandings are by no means confined to the profession of dentistry. We realize that some who are able and ought to pay for dental services rendered will try to get service without payment. This, of course, is not contemplated by any fair-minded person, much less by the Government. Registrants who are able to pay for the necessary work ought to do so, and those demanding very expensive work, or more than is necessary to fit them for military service, ought at least to pay the expense.

In order, however, to avoid any misunderstandings, and to prevent any possibility of abuse or scandal, I think there should be no attempt whatever to differentiate between those who may and those who may not be able to pay, so far as concerns the actual work necessary to fit for military duty. I think the rule ought to be clearly and fully announced, that any registrant who is sent to one of your members and presents himself for treatment, comes as a result of a statement that the work is to be done without cost to him, just as if he were already in the service and were being treated by army surgeons, and is to be given such treatment as may be necessary, without any thought or inquiry as to whether or not he is able to pay. If he voluntarily and without demand offers to pay what he can, or if he requests additional treatment beyond what is absolutely essential, that is a matter of agreement between him and the dentist.

I hope I have made myself perfectly clear, and am sure that you agree with the proposition I have advanced.

I hope that you will convey to the members of the League the assurance that the value of the magnificent patriotic work it has undertaken and is performing is fully appreciated not only by this office and by the War de-

partment, but also by all our people to whom it is day by day becoming better known.

Very truly yours,

J. S. EASBY-SMITH, *Lieut.-Col. N. A.,*
Chief, Law Division.

SOCIETY NOTES AND ANNOUNCEMENTS

NOTICES should reach the Office of the DENTAL COSMOS not later than the 11th or 12th of the month preceding that of publication.

TWENTY-SECOND ANNUAL MEETING

OF THE

NATIONAL DENTAL ASSOCIATION.

Chicago, August 5, 6, 7, 8, and 9, 1918,

AT AUDITORIUM AND CONGRESS HOTELS.

At this the Sixtieth Anniversary of Organized Dentistry the G. V. BLACK MEMORIAL will be dedicated. The unveiling of the monument will take place on Thursday, August 8th, at 2 P.M.

MONDAY, August 5th.

The Registration office will be open Monday morning at 8.30 o'clock.

The members of the House of Delegates will present their credentials and be seated at 10 A.M.

This will be the official business day of the meeting.

TUESDAY, August 6th.

9.30 A.M.

Seminar—The Management of Pulpless Teeth.

Six of the best-known scientific research workers will submit "evidence and not opinions" on the subject.

2.00 P.M.

Three Section Meetings.

The Section on Prosthetic Dentistry and Crown and Bridge Work will render a program on "Occlusion and Variable Occlusion" and "A Scientific Technic in the Construction of an Artificial Denture."

The Section on Oral Surgery and Anesthesia will present a program on "Cleft Palate and Harelip Procedures" and "Recent Progress in the Management of War Injuries of the Face and Jaws."

The Section on Orthodontia and Periodontia have arranged for the following program:

"A Classification of Pathological Conditions of the Mouth."

"Physiological Factors as Related to the Peridental Membrane, Cementum, and Bone in Tooth Movement."

"Orthodontic Appliances and the Gingival Tissue."

"The Histology and Development of Cementum."

"The Duty and Responsibilities of the Orthodontist in the Present War."

"The Necessity for Orthodontic Interference in Malocclusion of the Teeth."

8.30 P.M.

Military Dentistry—War Surgery.

The speakers at this session will be surgeons of national and international reputation.

WEDNESDAY, August 7th.

9.00 A.M.

Six Section Programs and Oral* Surgery Clinics.

The Sections on Operative Dentistry, Materia Medica and Therapeutics, Organization, Mouth Hygiene and Public Service, Research, The Preparedness League of American Dentists, and General Oral Surgery Clinics, will each present their programs in various rooms in the Auditorium and Congress Hotels.

2.00 P.M.

The Sections on Prosthetic Dentistry and Crown and Bridge Work, Oral Surgery and Anesthesia, and Orthodontia and Periodontia, will hold their second sessions.

8.00 P.M.

Canadian Dentists, Our Guests.

How fitting it is, when the young men of the Allied countries are freely and willingly giving their lives in the terrible conflict which is absorbing the attention of the entire world, when men and women in every station of life are making their first business the winning of the war, that the dentists of Canada and the United States should unite in holding their National meetings. The Canadian Dental Association will be the guests of the National Dental Association at this meeting,

and the program for the Third General Session for Wednesday evening will be furnished entirely by that society. In the United States we have long since learned to follow the advice of Ruskin:

"Gain all the knowledge you can;
Then use it for the highest purpose."

THURSDAY, August 8th.

9.00 A.M.

International General Clinic—150 Clinicians.

Clinics will be given by members of the Canadian Dental Association, and by representatives of forty states and Alaska—Unit Clinics, Special Clinics on Root-canal and Crown and Bridge Work.

LUNCHEON.

Luncheon to Our Ex-presidents.

Former Presidents of the American, Southern, and National Associations to be the guests of the Association at a luncheon in their honor by the members of the profession, who desire in this small way to show their appreciation of the valuable services they have rendered the profession and also to pay a just tribute to the Founders and Builders of Organized Dentistry.

2.00 P.M.

Dedication of the G. V. Black Memorial.

It has now been almost three years since the dental profession was deeply grieved to hear of the death of Dr. G. V. Black. Those who were present at the Panama-Pacific Dental Congress at San Francisco will never forget, when his death was announced just at the opening of the Congress, how the cloud spread over that vast audience. In matters pertaining to dentistry, Dr. Black was easily the master. If the world misses him, as it surely does, how much more do we miss him? It was our pleasure and privilege to live with him, speak to him, and feel free to consult him at any and all times. By his death the dental profession has lost one of its most cherished members; the world has lost a benefactor. All that was needed to erect a monu-

ment to his memory was for someone to say the word. That word has been said, and dentists from nearly every state in the Union, as well as from many foreign countries, have contributed to the fund for the purpose. What could be more appropriate, therefore, than to unveil the monument to this great man when the National Dental Association is holding its annual meeting in the city where, during the last years of his life, he lived and worked.

8.00 P.M.

Patriotic Services.

Men of international and national reputation will be on the program for this unusual meeting, men who are the recognized leading statesmen, surgeons, and divines of this age. It is quite fitting in this great war crisis that the dental profession should show its patriotic spirit by pledging anew its loyalty and devotion to our country. The speakers on this occasion will give the members of the dental profession an opportunity to hear the best men of the day discuss the vital problems that have to do with the present and future of our Republic.

FRIDAY, August 9th.

9.00 A.M.

General Session and Section Meetings.

The Sections on Operative Dentistry, Materia Medica and Therapeutics, Organization, Mouth Hygiene and Public Service, Research, and the House of Delegates and the last general session will be the climax of this great meeting—an anniversary meeting that will go down through the years as having established a NEW HIGH-WATER MARK in the history of dentistry.

REMEMBER THE SPLENDID TIME YOU HAD IN CHICAGO at the fifteenth anniversary celebration of the Chicago Odontographic Society in 1903, and the Golden Anniversary of the Illinois State Dental Society in 1914. Since these meetings several years have elapsed, and the Chicago dentists have profited by being hosts on these occasions. They now ask that they be given another opportunity to prove the foregoing assertion.

The Chicago Meetings.

THE following associations gather at Chicago at the time of the N. D. A. meeting:

NATIONAL DENTAL ASSOCIATION. Chicago. August 5th to 9th.

CANADIAN DENTAL ASSOCIATION. Chicago. August 5th to 9th.

NATIONAL ASSOCIATION OF DENTAL FACULTIES. Chicago. August 2d and 3d.

NATIONAL ASSOCIATION OF DENTAL EXAMINERS. Chicago. August 5th and 6th.

AMERICAN ACADEMY OF ORAL PROPHYLAXIS AND PERIODONTOLOGY. Chicago. August 2d and 3d.

AMERICAN SOCIETY OF ORTHODONTISTS. Chicago. August 1st to 3d.

ASSOCIATION OF MILITARY DENTAL SURGEONS. Chicago. August 7th.

DELTA SIGMA DELTA FRATERNITY. Chicago. August 5th.

PSI OMEGA FRATERNITY—NATIONAL ALUMNI CHAPTER. Chicago. August 5th.

XI PSI PHI FRATERNITY. Chicago.

[AT CHICAGO.]

Canadian Dental Association.

THE Canadian Dental Association has accepted the very kind invitation of the National Dental Association to meet with them in Chicago, August 5 to 9, 1918.

SYDNEY W. BRADLEY, *Sec'y.*

[AT CHICAGO.]

American Academy of Oral Prophylaxis and Periodontology.

THE fifth annual meeting of the American Academy of Oral Prophylaxis and Periodontology will be held August 2 and 3, 1918, at Edgewater Beach Hotel, Chicago, Ill.

GRACE ROGERS SPALDING, *Sec'y.*

[AT CHICAGO.]

American Society of Orthodontists.

THE eighteenth annual meeting of this society will be held August 1, 2, and 3, 1918, at the Edgewater Beach Hotel, Chicago, Ill.

This will be an excellent meeting. It is advisable to make your reservations early.

F. M. CASTO, *Sec'y,*
Rose Bldg., Cleveland, Ohio.

[AT CHICAGO.]

National Association of Dental Examiners.

THE next meeting of the National Association of Dental Examiners will be held in Chicago, Ill., August 5 and 6, 1918, at the Auditorium Hotel.

For further information address

J. A. WEST, *Sec'y*,
417 Utica Bldg., Des Moines, Iowa.

[AT CHICAGO.]

National Association of Dental Faculties.

THE next annual meeting of the National Association of Dental Faculties will be held in the Green Room of the Congress Hotel, Chicago, Ill., August 2, 1918, at noon. The Executive Committee will meet at 10 A.M. on the 2d. The meeting will continue through August 3d.

CHAS. C. ALLEN, *Sec'y*,
N. W. cor. 10th and Troost, Kansas City, Mo.

[AT CHICAGO.]

Delta Sigma Delta Fraternity.

THE thirty-fourth annual meeting of the Supreme Chapter of Delta Sigma Delta Fraternity will be held in the Florentine Room of the Congress Hotel, Chicago, on Monday, August 5, 1918, at 9 A.M.

Headquarters of the Fraternity will be at the same hotel, where the annual banquet will also be held in the evening in the Gold Room. (Notify Dinner Committee at once.)

By order of the Supreme Chapter.

HY. W. MORGAN, *Supreme Gr. Master*.
R. HAMILL D. SWING, *Supreme Scribe*.

[AT CHICAGO.]

Psi Omega Fraternity.

THE National Alumni Chapter of the Psi Omega Fraternity has established headquarters during the National Dental Association meeting at Room 230, Auditorium Hotel.

The business session of the National Alumni Chapter will be held in the New Ballroom of the Auditorium Hotel, Monday, August 5th, at 2.00 P.M.

The Psi Omega banquet will be held in the

Florentine Room of the Congress Hotel at 7.00 P.M., Monday, August 5th.

Psi Omegas who expect to attend the banquet should communicate at once with Dr. M. M. PRINTZ, 4235 Lake Park ave., Chicago.

Harvard-Tufts Training School for Dental Hygienists.

THE commencement exercises of the Harvard-Tufts Training-school for Dental Hygienists were held at the Hotel Thorndike, Boston, Mass., on June 21, 1918.

The program included a dinner, after which addresses were made by Dr. H. C. Bumpus, president of Tufts College, Dr. George H. Wright, Dr. Wm. Rice, dean of Tufts College Dental School, Dr. Henry H. Piper, all members of the administrative board of the school; Dr. Leila M. Taylor, director of the school, and Miss B. L. MacFarland, representing the graduating class.

Dr. Eugene H. Smith, dean of Harvard Dental School and chairman of the administrative board, presided, and awarded the certificates.

LEILA M. TAYLOR, *Sec'y*.

Forsyth Training School for Dental Hygienists.

ALUMNÆ ASSOCIATION.

THE Alumnae Association of the Forsyth Training-school for Dental Hygienists held its fourth meeting at the Forsyth Dental Infirmary for Children on June 20th. The Forsyth Alumnae were glad to have present the graduating class of the Tufts-Harvard Training-school for Dental Hygienists, with their supervisor, Dr. Taylor. Some Fones Training-school graduates practicing in Boston dental offices were also present, and many undergraduate dental hygienists of the Forsyth School, with their supervisor, Dr. Anna V. Hughes. Two very interesting speeches were delivered. One was given by Dr. Carl Lindstrom of the Massachusetts State Board of Dental Examiners, on "The Success of Dental Hygienists." Dr. Albert L. Midgley of Providence spoke on "The Ideal Dental Hygienist." After the meeting a social hour was enjoyed.

A. E. CHRISTIE, *Editor*,
Class of 1917.

G. B. Winter Exodontia Club.

THE exodontists of Minneapolis and St. Paul had their first formal meeting at the Minneapolis Athletic Club, May 19, 1918. The guest of honor was Dr. George B. Winter of St. Louis, the originator of a new technique for the removal of impacted lower third molars. Dr. Winter demonstrated the efficiency of his system by removing a large number of impactions, at a clinic.

As recognition of his contributions to science, the club honored him by naming

this, the first organization of its kind, for him.

HENRY B. CLARK, *President*.

CARL J. RICE, *Secretary*.

Iowa Board of Examiners.

THE next meeting of the Iowa State Board of Dental Examiners for the examination of applicants will be held in Iowa City, August 26, 1918, commencing at 9 A.M.

For further information address

J. A. WEST, *Sec'y*,

417 Utica Bldg., Des Moines, Iowa.

ORIGINAL COMMUNICATIONS

The Pathogenesis and Prophylaxis of Pyorrhea Alveolaris.

By Dr. MAURICE ROY, Paris, France,

PROFESSOR IN THE DENTAL SCHOOL OF PARIS; DENTIST TO THE HOSPITALS OF PARIS.

(Report presented to Section III, Dental Surgery and Therapeutics, of the Sixth International Dental Congress, London, 1914.)

(Continued from page 670.)

(II.)

Part II.

CHAPTER I.

THE ALVEOLAR LESIONS.

WITH the exception of the alveolar lesions, I have reviewed all the lesions which accompany the development of pyorrhea alveolaris. I have indicated the reasons for them. None of them, it appears to me, should be considered as the initial lesion which marks the first step in the development of the disease.

It remains to me only to examine the lesions of the osseous tissue, and, supported by clinical observations corroborated by morbid anatomy, to show that in fact the alveolar lesions antedate all others, and that it is their presence which permits the further evolution of the

pyorrhea, with its habitual symptomatic *cortège* and its complex lesions. This subject will form the second part of my work.

(1) *Clinical lesions.* To study pyorrhea in its initial stage, let us consider the relations of the different tissues of the alveolar dental region in normal man. For this purpose let us consider the mouth of an individual, twenty years of age, healthy, having teeth well arranged, and whose teeth and gums are sound.

If we examine the gingival region of such a subject, we notice that the gum is inserted exactly at the neck of the tooth, where it presents a very minute pad, which forms a space V-shaped in form—a sort of groove, rather than a cavity—which Mendel Joseph calls the

pericervical space ("gingival trough" of Hopewell-Smith). If we attempt to explore the proximal interdental spaces we shall see that even with the finest instruments we penetrate only with difficulty between the teeth, and there will always be a slight tearing of the gum; for normally this space is completely occupied by the alveolar tissues, ligaments, and gums. This person has little difficulty in cleaning his teeth. They clean themselves spontaneously by mastication, by virtue of the perfect anatomical relations of the dental arches with the cheeks, the lips, and the tongue, which rub against the teeth throughout almost the whole extent of their vestibular and lingual surfaces. He does not experience the least need of using a toothpick, for no food débris will remain in his absolutely closed interdental spaces.

Let us now examine this same individual at the age of forty years. Let us suppose that his constitution is slightly arthritic. He has taken suitable hygienic care of his mouth. His teeth and gums are always healthy. His teeth are always perfectly placed upon the alveolar arches, and normally occlude. Nevertheless, if we ask him he will tell us that at times he has to make use of the toothpick, because after meals it frequently happens that food débris remains between his teeth. If we explore these interdental spaces, we find that while, twenty years previously, access into these spaces was very difficult, we can now pass into them easily and with instruments of very large caliber.* We likewise find in the vestibular and lingual regions of

the mouth that the normal necks of the teeth are no longer in relation with the insertion of the fibro-mucous gum, and that the cementum is more or less uncovered.

Nevertheless—and I have assumed that our subject has followed the most efficacious hygienic precepts—the pericervical space has followed the gum in its recession, and has not been transformed into a pocket. There is no suppuration at the necks of the teeth.

We have here, however, a patient attacked by pyorrhea alveolaris (understanding this term always in a general sense as we have agreed to use it), since he exhibits the primary lesion of pyorrhea, viz, alveolar resorption. And if the patient were delinquent in the hygienic care of his mouth, if he had some trouble in what Godon has very justly called the articular equilibrium of the teeth, he would present, in the region of one or more teeth, no longer the clinical picture we have outlined, but that of pyorrhea clearly established, with the more or less deep gingival pocket which is characteristic of the disease, and with the complex symptomatic sequence which accompanies the evolution of this affection. What, then, has occurred in this individual, whose tissues are normal in external appearance, and in whom no local pathological cause has appeared to intervene?

If we examined the maxilla of this man by dissection, or if, more happily for him, we contented ourselves with making a radiograph, we should find that the alveolar borders have become notably lowered in height and present the lesions which J. F. Colyer has so well shown upon dried specimens, and presents in his work upon the "Pathological Anatomy of Periodontal Diseases."* If we made a section of the alveolar region of this same person, we should find there, in spite of his age, all the signs of senile alveolar atrophy, well described by Hopewell-Smith.†

* Simply because the abuse of the toothpick can produce lesions of the gum and of the ligament of the interdental space, it is not fair to assume, as many practitioners do, that the toothpick is responsible for the creation of interproximal gaps. These are produced spontaneously, and, in the large majority of cases, people begin to use toothpicks only when they feel the need as a consequence of the existence of abnormal interdental spaces, either through alveolar resorption, common in the case under consideration, or through caries, defective filling, or deviation of teeth from their normal positions.

* J. F. Colyer, *Ash's Monthly*, September 1913, p. 705.

† Hopewell-Smith, "Pyorrhea Alveolaris," *DENTAL COSMOS*, 1911, pp. 397 and 981.

This osseous atrophy is the primary lesion, entailing the resorption of the pericementum of the gum and the sequent denudation of the root of the tooth. The osseous lesions, in a word, have brought on all the others.

In order to demonstrate the exactness of the subordination of the modifications of the alveolo-dental ligament and of the gum to the osseous modifications, and supporting my argument by clinical findings, I shall take the example of a process diametrically opposite to that which I have just described, and in which the same sequence of phenomena is produced, but in an inverse order.

Teeth deprived of their antagonists present most often a vertical displacement, which is accompanied by loosening, and frequently by pyorrhea alveolaris. Yet individuals are at times observed in whom the absence of antagonists, if it has led to the vertical displacement of the teeth of the opposed jaw, has produced no loosening of the teeth, which are extremely firm in their alveoli and without any noticeable trace of denudation.

While the displacements observed in teeth deprived of their antagonists are ordinarily accompanied by a more or less considerable denudation of the root, which is in some degree forced from its socket, it may be established in these cases I have just mentioned that the root is only slightly or not at all denuded, and that the gingival mucosa is precisely adapted to the necks of the teeth, without trace of recession or of a pathological pocket—and this although the teeth may be considerably displaced, sometimes to such a point that they impinge upon and abrade the gum of the opposite jaw.

The alveolar walls are not resorbed, but, on the contrary, are thickened—as palpation of the region, and even at times direct vision, will show. If such a tooth be extracted, one learns that its resistance is always greater than that of its normally placed neighbors, by virtue of the greater resistance of its thickened alveolar walls.

There has, therefore, occurred here an

inverse phenomenon to that which accompanies pyorrhea. Without the influence of causes which we are not called upon to investigate here, and which elsewhere I have tried to explain,* the osseous tissue has hypertrophied, and under this influence the tooth is vertically displaced, and with it the tissues whose framework is the bone, i.e. the pericementum and the gum.

Here is a very clear example of the subordination of pericemental and gingival modifications to osseous modifications, and in this fact I believe we find a confirmation of the primordial rôle played by the primary osseous atrophy of pyorrhea upon the pericementum and the gum, which follow their bony framework in its atrophic or hypertrophic evolution.

(2) *The anatomico-pathological lesions.* The truth of the location of the initial lesions in the alveolus and of the subordination of all other lesions to those of the osseous tissue, is not only furnished by the clinical data, but, if we control the clinical data by those supplied by pathological anatomy, we shall find confirmation of the considerations we have just adduced.

Indeed, if we examine numerous sections of cases of pyorrhea at different stages, as presented in the works of Hopewell-Smith (*DENTAL COSMOS*, 1911, p. 397), and those of Mendel Joseph (*L'odontologie*, 1913, vol. ii, p. 49), and particularly those of the least advanced cases of the disease, we find that the osseous alterations always have progressed much farther than the gingival lesions; and we clearly see that the bone is already absorbed, while the gum and ligament are still attached to the cementum at a point near the neck of the tooth, and are, as yet, only slightly inflamed.

Hopewell-Smith† describes the osseous lesions thus:

* Maurice Roy, "De l'Allongement des Dents dépourvues d'antagonistes," *compte rendu de Congrès dentaire national de Bordeaux*, 1895, p. 126.

† Hopewell-Smith, *DENTAL COSMOS*. 1911, vol. liii. p. 405.

The alveolar bone exhibits, even before the gum, the most important metamorphoses that have occurred. Briefly, they are those produced by the process of halisteresis (perhaps a form of osteomalacia). Not only is the free margin of the bony socket absorbed by osteoclasts near the upper and lower parts of the cervical regions of the teeth, but deep down, by the radicular portion, giving the surface an eroded appearance; moreover, there is also a decalcification of the most superficial portions. The bone becomes transformed into an osteoid tissue through loss of its calcium salts, then passes into an intervening fibrous tissue, and finally is attacked by the inflammatory exudation and cells, its bays and recesses becoming meanwhile greatly enlarged and filled with loose soft tissue, and the Haversian canals enlarged and irregular, the condition being termed osteoporosis.

The osseous lesions, indeed, are not confined to the alveolar borders. Equally well may be recognized a process of osseous absorption in the apical region; but, by virtue of the anatomical relations of the region, it is the resorption of the alveolar borders which, breaking the gingival insertion at the neck, will condition the development of the symptomatic ensemble termed pyorrhea alveolaris.

If the lesions of the alveolo-dental ligament preceded those of the alveolar septa, and were the cause of their resorption, this could only be brought about as a result of an inflammatory process, which may possibly exist when the pyorrhea is definitely established, but which is lacking at the initial period, as we have just shown. The osseous lesions would be less advanced than the gingival and pericemental lesions, which is never the case in the preparations which we have referred to, and which constitute the most recent and complete histological studies we have upon pyorrhea.

Mendel Joseph,* although he does not formally specify the primary lesion of pyorrhea, says:

The alveolo-dental ligament represents the anatomical center around which the pyorrhetic lesions develop, but it does not appear

to be the pathological center. In the majority of preparations which I have examined, the alterations of which it is the subject have appeared secondary to the lesions of the adjacent tissues.

If this author considers certain osseous lesions as secondary, it also means that in certain cases examined by him, on the contrary, they appeared clearly primary: "The gingival lesions can no longer be invoked as the initial factor, for they are scarcely marked, and nevertheless the alveolar walls are the victim of a work of profound rarefaction."*

In connection with a recent paper read before the Odontological Society of Paris, he presented several still unpublished sections, and, apropos of one of them, said that while he expected to find pyorrhea at its very beginning, he had been surprised to find that the osseous lesions were much farther advanced than the peripheral lesions had indicated.

Hopewell-Smith† clearly confirms this phenomenon, and concludes his work with the statement that pyorrhea "depends essentially upon an osseous lesion, upon a bony atrophy." This idea appears, indeed, to result from the ensemble of the preparations of this learned observer.

CHAPTER II.

PRECOCIOUS SENILITY.

The osseous changes just described are the result of a precocious senility. Hopewell-Smith arrived at this conclusion, and I am absolutely in accord with him upon this point.

This idea of the precocious senility of the alveolo-dental tissues was first expressed, I believe, by an Englishman, Thomas Bell,‡ in 1835, and was taken

* *Ibid.*, p. 68.

† Hopewell-Smith, *DENTAL COSMOS*, 1911, p. 410.

‡ "A considerable absorption of the gum and of the alveolar process, provoking the denudation of a large part of the roots of the teeth, is sometimes produced without the accompaniment of any appearance of disease, and without any serious organic trouble. In forming an opinion upon cases of this sort and of those in which the loss of substance is

* Mendel Joseph, *l'Odontologie*, 1913, p. 69.

up in 1892, in France, by Paul Dubois. Likewise, this opinion is defended in America by Talbot, and in Germany by Robert Baume. If these several authors are not in accord in regard to the seat of the primary lesion, they are unanimous at least upon one point, namely, that precocious senility causes pyorrhea alveolaris. This conception of precocious senility as the cause of pyorrhea is to me of great interest, for it implies, in itself, outside of the primary local lesions, the intervention of a general factor, whose influence is primordial.

The clinical picture which I have traced of an individual examined at twenty years of age, and again at forty, will be confirmed, I am sure, by all practitioners who have practiced sufficiently long to have been able to follow attentively the same individuals throughout many years. Now, the anatomical

associated with a more or less morbid state, it is necessary to recall that teeth disappear in old age generally in an identical fashion, *i.e.* the destruction of their support by absorption of the gums and of the alveolar process. And, as this first step toward a general decay commences at different periods, according to temperament, it can surely, in many cases, even among persons not beyond middle age, be considered as a sort of precocious senility or senile decay—at least, as regards these parts of the body. However, it is not always necessary to hold it (old age) responsible; for sometimes senile decay is met with in young subjects, and assuredly it proceeds from the same causes as those which are considered responsible for a similar loss of substance in these parts when they are accompanied by a more or less morbid state. These differences can, perhaps, be attributed to the difference of constitution, or to the greater or less period which has elapsed since the primary cause of the affection, whatever it might have been, supervened. Although the gradual loss of gum and alveolar substance occurs occasionally without any serious local or constitutional morbid action, it occurs more frequently by derangement of the digestive organs or some other immediate or remote constitutional cause; and then it is invariably accompanied by a morbid condition of these same parts." (Th. Bell, "The Anatomy, Physiology, and Diseases of the Teeth." 2d ed., London, 1835, p. 211.)

modifications which are produced in the person whom I have taken as an example are evidently not due to local, but to general causes. They are associated with the vitality, the general nutrition, of the individual.

Alveolar resorption is not alone a consequence of pathological troubles, but it is also the result of a pathological process. Hopewell-Smith* says:

Absorption of each alveolar process of the jaws is a common occurrence; it is the rule in man and the lower animals. The more aged the individual the greater the loss of this bone, with the concomitant shedding of its dental occupants. The teeth of dogs, cats, monkeys, and other animals, either in a domesticated environment or *in natura fera*, become loose as time passes by, as a direct consequence of the absorption of their sockets—a physiological process. Man becomes more and more inclined to be edentulous as he advances in life—a part of the decadence of his vital powers. Thousands of skulls of aged people exist where the teeth remain *in situ*. This is due to the splendid natural physique of the owners. But in probably eighty per cent. of individuals living in highly civilized communities it is the normal condition for the alveolar processes to atrophy and shrink, for the gum tissues to become thinner and degenerate, and for the roots of the teeth to become exposed.

Senile atrophy of the alveolar borders is, then, a physiological process when it occurs at an advanced age; but, according to R. H. Hofheinz (DENTAL COSMOS, 1913, vol. lv, p. 630), senility is not necessarily a question of years. Some persons are old at thirty, if judged by their teeth; and Paul Dubois has already emphasized the fact, which I believe has not been sufficiently emphasized, *e.g.* "In a number of people affected by expulsive periodontitis, there is a precocious atrophy of the hair follicles. The hairs become white, and are soon lost."

As regards this I have been curious, but hitherto have not collected a sufficiently large number of observations. In some individuals the teeth first at-

* Hopewell-Smith, DENTAL COSMOS, 1911, vol. liii, p. 989.

tacked by senile alveolar absorption are those situated on the same side as that on which the hair first became "precociously gray."

If, as Hopewell-Smith says, halisteresis is the primary process of osseous resorption, this fact would furnish the explanation of the pathological relation, suggested by Paul Dubois, between the bleaching and falling out of the hair and pyorrhea alveolaris, since halisteresis seems rather to be due to the action of the nervous system,* and since nervous inter-relations between the teeth and hair are known—inter-relations upon which Jaquet, in France, has particularly insisted in treating of the etiology of alopecia areata.

But, whatever be these accessory phenomena, there exists, as was very clearly shown from the preparations of Hopewell-Smith, a formal identity between the senile resorption of the alveolar borders and the osseous resorption of pyorrhea at its beginning. Doubtless, when cases of further advanced pyorrhea are examined, phenomena different from those of senile atrophy are found; but at this stage other causes have intervened in addition to the primary process. This is why I must continue to insist that in order to discuss the nature and origin of pyorrhea, one must refer to the cases in the initial period of the disease, and not to cases where the disease is already advanced—for too many accessory causes then appear which will mask the primary lesions.

The objection made to the nature of the senile atrophy of the bone in pyorrhea is that certain osseous lesions observed are of an inflammatory nature, and not atrophic; but this condition explains itself, since to the primary phenomenon, purely atrophic in the beginning, are added later, as we shall see, other secondary phenomena which affect the gum and the pericementum, and which, being inflammatory in nature, provoke in the underlying bone phenomena analogous to those which are observed in all inflammations occurring under similar conditions.

In simple gingivitis, for example, alveolar resorption can be observed; yet this feature has no claim to figure in the category of what is called "pyorrhea alveolaris." It is simply a resorption by inflammatory propagation of a common process, and this feature does not constitute a clearly determined disease such as that we are accustomed to consider under the name of pyorrhea alveolaris. It is precisely from this confusion of cases which are not similar that some of the errors arise concerning the nature of pyorrhea.

From the considerations I have just adduced it results that if one desires to study pyorrhea alveolaris in its earliest phases, and in cases where it exists uncomplicated, *i.e.* without association with any accessory process, the findings of the clinic and of pathological anatomy are united in affirming that *Precocious senile alveolar atrophy is the initial lesion of pyorrhea, constant in occurrence, and preceding all other lesions.*

To what cause may be attributed this precocious senile alveolar atrophy? I do not intend to discuss this subject at length; that would exceed the limits I have assigned myself. It might be developed as a separate thesis, the elements of which would be found in the already mentioned interesting study of Julien Tellier, in which is contained a synopsis of the general causes invoked as provocative causes of pyorrhea.

I can say, however, that it seems probable that a large number of causes can intervene to call forth this precocious senility, and that all diatheses can doubtless lead to it. Arthritism, in particular, by virtue of its accompanying circulatory disturbances and of the vaso-motor and trophic phenomena it provokes, is quite naturally the diathetic condition which is most frequently the cause of this precocious senile atrophy, and consequently of pyorrhea alveolaris.

This atrophy could be due to vaso-constrictor phenomena, which would manifest themselves more particularly in terminal points, as the alveolar borders, which according to Talbot are adventitious and transitory organs. This

* Julien Tellier, *loc. cit.*, p. 97.

is why, contrary to Endelman's opinion, pyorrhea improves not by rest, but by the re-establishment of normal mastication, this favoring the circulation of the alveolo-dental articulation.*

From the fact that pyorrhea alveolaris is an affection resulting from a primary general cause, there arises an important point, namely, that the suppression of local causes, whose considerable rôle in the evolution of the disease I shall immediately show, is unable alone to arrest this disease. Indeed, if alveolar resorption due to the extension of a gingival inflammation by calcareous deposits is *completely* arrested after disappearance of the tartar and the gingival inflammation thereby induced, and if this resorption is not resumed, while the local conditions remain satisfactory, the disease is not pyorrhea. *In the exclusion of every local adjuvant cause this affection is slowly progressive, while there exist the general causes which provoke precocious senile alveolar resorption.*

CHAPTER III.

THE EVOLUTION OF PYORRHEA ALVEOLARIS.

Precocious senile alveolar resorption constitutes the first phase of pyorrhea alveolaris. However, if this disease remained at this first stage, it would never

have earned the name of pyorrhea. We must now see in what order the phenomena following this resorption succeed each other, and the rôle played by the various etiological factors wrongly cited as primary causes, but which are the adjuvant causes so important in the development of the disease.

I have said that the initial alveolar resorption brings in its train the corresponding resorption of the pericementum and of the gum. If the gingival resorption makes parallel progress with the osseous resorption, the accidents are limited to the denudation of the tooth root. The gingival fibromucosa remains firmly inserted in the cementum at a plane more or less distant from the normal neck, but there is no suppuration at the neck, and no gingival pocket except the normal pericervical groove (gingival trough, Hope-well-Smith). *There is no noticeable loosening of the teeth, even when the radicular denudation is very extended, if there is no pocket formed.*

All disturbances of articular equilibrium of the teeth, malocclusion, malposition, absence of approximal or antagonistic teeth, will favor the production of precocious senile alveolar resorption; for already, indeed, these have by themselves created abnormal relations between the gingival insertion and the necks of the teeth, except in the unusual cases above cited.

This is why pyorrhea begins sooner in regard to teeth affected by these disturbances of equilibrium, though these, of themselves, could not call forth the disease; for in certain individuals refractory to pyorrhea, disturbances of dental equilibrium are encountered with no sign of pyorrhea, even after they have passed middle life—by virtue of the absence of alveolar resorption from general causes indispensable for the beginning of the disease.

As long as there is a parallelism between alveolar resorption and gingival resorption, no pocket is produced at the neck of the tooth. However, this parallelism may be destroyed. And accord-

* This would justify the very interesting remark of Wheeler, who, having examined a large number of ancient crania and not having found any indication of pyorrhea, and very slight indication of tartar, thinks that this is due to the more vigorous exercises practiced by man during mastication in primitive ages, which led to a greater vitality of the periodontal tissues, and rendered them less susceptible to attacks by micro-organisms which have always existed in the mouth, without taking into account the fact that, at this period in the development of man, affections due to diminishing nutrition would be infinitely more rare, in consequence of the much greater physical activity of the race in primitive ages. (Wheeler, "Some Observations upon the Obscure Etiology of Pyorrhea Alveolaris," DENTAL COSMOS, 1906, vol. xlviii, p. 473.)

ing to the observation of R. Baume,* the bone may be more rapidly absorbed than the gum. To bring this about, it is sufficient that a marginal gingivitis be set up at any point of the neck. There results immediately a slight hypertrophy of the gingival pad, which increases the normal pericervical space. From a simple gingival trough, which is its normal state, it becomes a small pocket, in which organic débris of all sorts from the mouth collects, and serves as a culture medium for innumerable micro-organisms.

Under the shelter of this small pocket, calcareous deposits, originating from the saliva, and conditioned, perhaps, by the extravasated blood or pus, are deposited upon the denuded cementum, and increase, at the same time, both the causes of gingival irritation and the causes of infections.

Two new accessory elements of the disease, infection and calculi, have, then, intervened at this moment, and pyorrhea arrives at maturity, with the formation of the pocket at the neck, which will precipitate the development of the disease. Gingival inflammation is conveyed to the pericementum and to the alveolus, and phenomena of osseous resorption of an inflammatory nature are added to the phenomena of senile resorption, and augment the divergence from parallelism between osseous resorption and gingival resorption.

Indeed, if inflammation produces in the bone phenomena of resorption, the same does not hold good for the gum, which, on the contrary, is hypertrophied by the same process, and which, sustained by healthy or less affected portions which surround it, ceases to follow the alveolus in its process of resorption, which at the beginning was senile but is now inflammatory. The pocket deepens more and more, protecting the increasingly numerous micro-organisms, which there produce pus in abundance, and aggravate thus all the pathological phe-

nomena previously existing, and upon whose progress I need not dwell, for they are now too well known to call for any discussion.

In this descriptive picture which I give of the disease, I have followed a methodical order, with the view to rendering more clear and more explicit the rôles, respectively, which I consider should be attributed, in the evolution of pyorrhea, to each of its etiological elements; but, for pyorrhea, as for the majority of other diseases, although this methodical evolution may be observed, yet it is often modified by accessory conditions which may mask the real conditions.

It is thus that gingivitis, which I have indicated as being consecutive to pyorrhea alveolaris, may exist previously to the development of pyorrhea; but that does not modify at all the reality of the succession of pathological phenomena which I have indicated. The only difference lies in the fact that in the picture which I have traced above, more or less time may elapse between the phenomena of alveolar resorption and the formation of the pocket, while, if gingivitis exists previously to alveolar resorption, the formation of the pocket will *immediately* follow the establishment of *precocious senile alveolar resorption*. And this is why a large number of observers, seeing only the previous gingivitis, attribute solely to this the formation of the gingival pocket, whose production, I think I have demonstrated, is a phenomenon preceded by much more complex and deeper causes than the simple local phenomenon which strikes the eye upon observing the established disease. These are exactly the deep causes which explain why a gingivitis may never be followed by pyorrhea in one individual who presents all local requisite conditions of infection, while the disease will occur in another individual who may present only slight infections and inflammatory conditions.

In gingivitis the essential factor of pyorrhea, precocious alveolar resorption, will be lacking, and this disease will not appear—even at times in aged individ-

* R. Baume, "Atrophie alvéolaire précoce et Pyorrhée alvéolaire," *Scheff's Handb. d. Zahnheilkunde*, 2d ed., vol. ii.

uals, who, if judged by their alveolar borders, will be found to be exceptionally young.

This also explains why such an individual, whose mouth is foul and whose gums have been inflamed for thirty or forty years without hitherto experiencing any apparent trouble in the vitality of his teeth or in their mechanical resistance, one day suddenly notices the appearance of a characteristic pyorrhea, because a precocious alveolar resorption, connected with some general constitutional trouble, has developed. At this moment, gingivitis, often existing from infancy, and hitherto having led to no profound trouble of the alveolo-dental articulations, becomes immediately associated with the precocious senile alveolar resorption, to produce mature pyorrhea with a rapidity varying with the degree of preparation of the infectious terrain.

As is seen in this portrayal, which accurately corresponds with clinical data, the different elements involved as causes of pyorrhea find their logical place in the evolution of the disease, and there is clearly seen, I think, the subordination of all other phenomena to precocious senile alveolar atrophy, the initial lesion. But in this complicated series, in which lesions may almost without interval be added one to another, and in some manner be confounded in a common evolution, it is not easy to establish the part assignable to each of the causal elements, while it is especially difficult to establish their sequence.

Therefore it is necessary to study pyorrhea at a sufficiently early period and in individuals in whom it is not yet associated with secondary phenomena which are but complications of the primary affection.

Part III.

CHAPTER I.

THE PROPHYLAXIS OF PYORRHEA ALVEOLARIS.

The majority of authors who have written upon pyorrhea all realize a part of the truth concerning the predisposing causes which at times play an apparently

sufficiently important rôle to mask almost completely the initial cause. This condition is not strange, because it is incontestable that the treatment of these adjuvant causes (disturbance of articular equilibrium, gingivitis, etc.) has considerable influence upon the improvement of pyorrhea.

Indeed, once pyorrhea is made possible by the occurrence of its primary lesion, the precocious alveolar resorption would not pass on to the mature condition, that condition marking the serious state of the disease, if one of the local adjuvant causes did not intervene. This is why, although this disease be traceable to a general cause, the efforts directed against local, adjuvant causes have such an influence in prophylaxis.

(1) *General causes.* To combat the general causes is a delicate task, variable according to the different systemic conditions likely to provoke precocious alveolar absorption, and in this treatment the dentist will often be a useful collaborator with the medical practitioner, if only to recognize the appearance of this pathological phenomenon indicative of a particular diathetic state.

I cannot here elaborate upon this general treatment, which obviously will vary with the cause provoking alveolar resorption. This treatment has great importance, as much from the standpoint of general as of local health, since we have shown that pyorrhea is gradually progressive, while there exist general causes provoking precocious senile alveolar resorption.

But this general treatment is important, and if it is not to be neglected it is necessary to recognize thoroughly that in the actual state of our knowledge it can exert only a restraining and remote influence upon lesions, once they have arisen. On the contrary, with the proscription of all the adjuvant causes of pyorrhea, local treatment entirely in the hands of the dentist will have the happiest effects upon the evolution of the disease, either by preventing its arrival at maturity, or, if that has occurred, by causing the disappearance of the secondary elements and by re-establishing the

health and functioning of the tooth as far as the stage of destruction of the tissues permits.

(2) *Local causes.* The gravity of pyorrhea in its mature form is known. The dentist should, therefore, apply himself most energetically to the prophylaxis of the local causes. In this respect his rôle is a responsible one, and regretfully he must confess that he most often neglects it, because through ignorance of the true pathogenesis he is not able to prescribe to his patients preventive hygienic measures, nor to indicate means of avoiding the development of this disease, dreaded for its local consequences.

This last point I would develop in closing, for it is the logical conclusion from pathogenic deductions which I have elaborated perhaps a little too tediously, but whose importance from the prophylactic viewpoint appears to me such that I insist upon it with all the ardor of a conviction based upon minute observation in a large number of patients.

The result of the considerations I have just developed is to teach that prophylaxis should be directed to two objects; namely, particularly to combat traumatic causes, but also to combat gingivitis and the infection which it represents.

I shall not expatiate upon the prophylaxis of traumatic causes, as this is a phase of the subject on which all authors are in accord. I shall confine myself to saying that the dentist should direct his efforts toward the elimination of all causes leading to a disturbance of the articular equilibrium of the teeth and favoring precocious alveolar resorption.

Such care should be exercised not only at the period when patients are particularly susceptible to the disease on account of their age, but also (and even more emphatically) from youth on, while correcting dental malpositions and conserving the dental organs.

It should never be forgotten that the loss of a single tooth in youth, although it may not cause any great apparent inconvenience during twenty or thirty

years, may be, at a given moment, the provocative cause of the development of a pyorrhea which will occasion successively the loss of all the teeth in the mouth if the appropriate treatment, often long and difficult, is not applied. Particular attention should be given to the insertion of fillings, which should always restore the forms of the teeth, and, above all, to maintaining their approximal contact. Attention to all these precautions will result, as we have seen, in the removal of the causes favoring alveolar resorption.

All dentists are in accord as to the importance of the hygienic care of the mouth as a means of avoiding infections and gingivitis, but because of a misunderstanding of the real mechanism by which pyorrhea develops, they do not give sufficient attention to certain particular points which are the cause of the development of this affection among persons who regularly brush their teeth, and in whom, even though resorption from a constitutional cause cannot be avoided, pyorrhea should never reach its mature form.

(3) *How does pyorrhea develop notwithstanding the fact that patients brush their teeth?* To make myself better understood, I shall refer to the clinical example which I took in the course of my description. It is the hypothetical case of an individual having all his teeth, healthy, normally arranged, and well supported.

At his twentieth year we examined him. His gingival attachments were perfect; and, even with very fine instruments, we could not pass into the interdental spaces, which were entirely filled by the normal gingival pads, without a slight tearing of the tissues.

At his fortieth year we re-examine this same patient, who is slightly arthritic, but whose teeth have always been healthy and normally placed. We notice then that he is led to make use of a toothpick, because food débris remains in his interdental spaces after eating; and while twenty years previously we passed only with difficulty between the teeth, we notice now that relatively large

instruments easily pass into the interdental spaces. Likewise we notice that the normal necks of the teeth are no longer in relation with the attachment of the gingival fibromucosa, and that the cementum is exposed to some extent, but no gingival pocket exists.

We have said that this patient was affected by pyorrhea alveolaris in its first stage, since he presented precocious senile alveolar resorption. Let us now see how this pyorrhea will evolve toward maturity; and this clinical picture will be, I think, the best illustration from which to develop the prophylaxis of the disease.

We have taken as an example an individual brushing his teeth regularly. If, then, at forty years, the mouth being in the state we have described, he continues to brush regularly the *gingival necks* of the teeth with the same care as previously there will result no grave inconvenience from this alveolo-gingival resorption; the tooth will maintain its almost normal solidarity, even with quite extended resorption; the uninflamed gum will remain firmly attached to the new neck of the tooth, and there will be no suppuration.

But at this period these hygienic conditions are difficult to maintain, for many reasons: (1) The cementum of the tooth is often slightly sensitive, especially if the patient continues to use a powder dentifrice; and this is one reason why his toothbrush instinctively does not pass over the denuded areas. (2) The new gingival neck is subjected to the cleansing effect produced by food attrition, and the friction of tongue, lips, and cheeks, less than is the normal neck. (3) This resorption being generally unknown to the patient, he continues at forty years brushing his teeth as he did at twenty; his brush, by an automatic movement, passes always at the same level, so that the normal neck of the tooth may still be brushed in a perfect manner (it may even produce, at this level, the so-called chemical erosion, from excess of brushing with powders), while at the new gingival neck, which escapes brushing, tartar and

deposits of every sort collect, which will provoke gingivitis and the formation of gingival pockets by the mechanism which we have described.

It is thus that pyorrhea is definitely established, in spite of the brushing of the teeth three or four times a day.

(4) *Dental errors.* Yet it is necessary to say that in a large number of cases the dentist does nothing to correct these bad practices of his patient, which may lead to the loss of all the teeth. The dentist placidly assists in the development of a characteristic pyorrhea, which too often he believes himself powerless to prevent. He not only does nothing, but (and this is a graver error) he often does worse; for, as a result of a grievous diagnostic error, taking effect for cause, he gives to his patient advice which will aggravate the condition and precipitate the evolution of the disease.

Indeed, if the patient, remarking the denudation of the necks of his teeth, asks advice of his dentist, this phenomenon is often attributed to an excessive brushing of his teeth; and the advice given is to use soft bristles, sometimes as soft as those of a shaving-brush. The dentist advises brushing the teeth solely in a vertical direction, which distinctly fails to clean the pericervical groove—or precisely that part of the tooth which most needs cleaning.*

In substance, the dentist advises the patient to avoid brushing his gums, thus aggravating the condition of his patient, in whom pyorrhea will evolve now without hindrance.

This is exactly comparable to forbidding brushing the head to one losing his hair from senility, under the pretext that it is the brush which is making his hair fall out, thus allowing dirt to accumulate on the head—which will accelerate

* Indeed, in one direction the brush passes as a bridge above this gingival groove, and in the other direction it crowds organic debris therein, and thus favors the formation of a pocket. This manner of brushing, then, should not be employed to the exclusion of any other, especially since the interproximal spaces of the teeth may be perfectly cleaned by horizontal brushing with a stiff brush.

the loss that it was intended to prevent.

I would not, before such an eminent assembly, which includes the professional *élite* of the entire world, give the impression that I am championing puerilities upon such a subject as that I have chosen, but when one has to combat such an affection as pyorrhea, which develops in subtle and silent fashion, and which attracts attention only when it has reached an advanced stage, one must not fear to descend from the high summits to emphasize these small facts of daily practice and to show their sad effects upon the development of the disease.

When the lamented W. D. Miller, after observing for years the effect of brushing the teeth with different brushes and powders used by patients, showed the cause of the development of so-called chemical erosion, he did more to add to the knowledge and prophylaxis of this affection than was accomplished by all the microscopic researches made by him and others upon the subject.

The attentive observation of the facts, then, shows that as a result of these small causes the grave disorders of pyorrhea develop whose primary lesions I have indicated. The following aphorism may then be formulated: All dentists ought always to keep in mind that *Pyorrhetic pockets are formed around a tooth only when one point of the gingival neck of the tooth cannot be maintained in a satisfactory state of cleanliness.*

(5) *Advice to give to patients.* By the maintenance of cleanliness, as perfectly as possible, of the gingival necks of the teeth, the dentist will combat the development of pyorrhea. He will attain this result, not only by his operative procedures, but also by his surveillance over the teeth of his patients, and by judicious advice. He must arrange with them to pay him regular visits, when he can examine the necks of all the teeth. He must point out to them the most vulnerable places, and especially those which are insufficiently brushed, so that his patients can correct vicious habits of brushing too automatically. He must demonstrate to

them the importance of brushing this *gingival neck*, which is modified by age or general constitution. He must show them that the toothbrush should always follow this neck as it ascends along the root as the result of this precocious senility. He must explain to them the nature of this precocious senility, which can be controlled only by general treatment, the effects of which can but slowly become manifest. He must show them that this general state of the constitution and of the mouth will have serious consequences for the teeth only if they neglect this cleanliness of the gingival neck: that the radicular denudation which they present is not a result of brushing the teeth, but quite the contrary, a result of the general disease. Finally the dentist must tell them that, the disease already existing, the sole danger resides in the absence of parallelism between osseous resorption and gingival resorption, and that it is necessary to become resigned to a slight denudation at the necks of the teeth, otherwise healthy and firm, rather than to have gums less resorbed, but with loose teeth, whose condition grows worse daily.

The majority of patients, however little care they give to their teeth, easily understand these explanations, realize their importance, and sincerely try to attain the goal which has been pointed out to them, because they have understood its motive and feel directly interested in its realization. The result will be a very rapid amelioration of the condition of the gums and the disappearance of the sensitiveness of the necks of the teeth (provided they do not use powder, paste, or soap); these improvements will demonstrate the excellence of a treatment for which they will not fail to be grateful to the dentist.

There is still one point to which it is proper to direct the attention of the patient, *i.e.* the condition of a pyorrhetic tooth grows worse, the less the force of mastication is exercised upon the tooth. Leaving out of account prosthetic restorations, which may at times be of advantage to pyorrhetics, it must be demonstrated to them that they

should not avoid biting upon a tooth because it is slightly sensitive as the result of very mild inflammation; that, upon slight insistence, they will find the sensitiveness disappear at the end of a few moments; mastication may thenceforth be performed without effort, and the nutrition of the alveolar tissues will be improved by this procedure in place of being lessened by the inactivity of the articulation.

In closing this article, I do not pretend to have solved the numerous problems of pyorrhea alveolaris; but I think I have accomplished my purpose, which was to bring some order and clarity into the contradictory phenomenal elements furnished by the works of my predecessors.

Supporting my contentions by the means most familiar to me, that of clinical observation, which I have shown to be in accord with the most recent work on pathological anatomy, I have sought to establish the relations of these diverse elements, and to present to you finally what I believe to be the logical and true evolution of the disease.

I consider that an exact conception of the development of pyorrhea is intimately associated with its prophylaxis. That is why I should be very happy if this communication should be a useful contribution to the study of this disease and to the battle against an affection which is the despair of the patient.

Conclusions.

(1) The term pyorrhea alveolaris is applied to a disease characterized, in its advanced period, by the presence of a more or less deep gingival pocket at the neck of the tooth, with corresponding denudation of the root over all that portion which comes into relation with the pocket.

(2) Pericemental abscesses upon vital teeth are not due to gouty tophus; these are pyorrhetic abscesses, formed in a serpiginous pocket, whose opening at the neck is unrecognized by virtue of its location, being situated at a point apart from the gingival abscess.

(3) The initial lesions of pyorrhea alveolaris can be determined only by the

study of the disease at its initial period, *i.e.* at a time when they are not masked by other associated affections.

(4) Precocious senile alveolar resorption of the alveolus is the initial lesion of pyorrhea. It is constant, and precedes all others.

(5) This resorption is of an absolutely general origin, since it can occur independently of any local cause.

(6) All local causes, invoked as the cause of pyorrhea alveolaris, are only adjuvant causes, since they can exist without pyorrhea, and since this disease—notably at its initial period—can exist in their absence. This would be inadmissible if they played the rôle of primordial causes.

(7) In the absence of any local adjuvant cause, pyorrhea slowly progresses as long as the general causes exist which provoke precocious senile alveolar resorption.

(8) Pyorrhea is established by its primary lesion, precocious-alveolar resorption; but it would not reach its advanced state, that which marks the serious period of the disease, if none of the local adjuvant causes intervened to complete the primary lesion.

(9) The prophylactic treatment of pyorrhea, leaving out of consideration any general treatment, will emphasize a disregard of all adjuvant causes (disturbance of articular equilibrium, infection, gingivitis, etc.).

(10) The normal functioning of the teeth affected with pyorrhea is an element favorable to their organic resistance. It should always be re-established, if it has been destroyed.

(11) The hygiene of pyorrhetics should always be inspired by this essential principle; that the pyorrhetic pockets are formed around a tooth only when any point of the gingival neck of this tooth cannot be kept in a satisfactory state of cleanliness.

(12) The dentist should, therefore, undertake the education of his patients, whose co-operation is indispensable in the prophylaxis of pyorrhea; and, by a regular surveillance, he should treat the slightest complications of the disease.

Conservation of Time in Teaching Dental Students.

By EUGENE S. TALBOT, M.D., D.D.S., Chicago, Ill.

CONSERVATION of time and money is the watchword in every department in these stirring war times. How to obtain the most out of the least expenditure of time and money is the crying need in every walk of life.

The art of ship-building, the manufacture of munitions of war, the production of food products for feeding the armies and the peoples of the world, have all been placed upon a scientific basis. The fully developed and equipped soldier ready for active service, which has required three or more years to produce in European countries, is now prepared in America in one year or less by intensive training. A prominent colonel in the United States army told me that one American soldier was as good in fighting qualities as five German soldiers.

At the present time the medical teachers throughout the country are engaged in formulating plans whereby the medical student and the trained nurse may be properly equipped to enter active service in the shortest possible time. The report of the Council on Medical Education,* under "Continuous Sessions in Medical Schools," is as follows:

At the conference held in February, the chairman of the Council, who is a member of the Surgeon-general's staff at Washington, presented a scheme for a continuous session in medical schools. The scheme outlined suggested that, for the duration of the war, each year be divided into three periods of four months each, these sessions beginning in October, February, and July of each year. It was shown that the student could enter on the study of medicine at the beginning of any one of these periods, and continue for eight successive periods of four months each,

at which time he would graduate and enter upon an intern service of one calendar year. This would require just four calendar years, when he would be ready for active service with the army. It was argued that by the adoption of this or some similar scheme the summer periods heretofore looked on as a vacation time would be utilized; the extensive teaching plants would be kept in continuous operation, and students would be graduated from nine to twelve months earlier than under the methods heretofore prevailing. Under this scheme the present junior class would be graduated four months earlier; the present sophomore class would be graduated eight months earlier, and the present freshman class would be graduated a year earlier, than under the former method. It was argued also that since there would be no vacations for the boys in the trenches, or for the medical officers in the service, there appeared to be no reason why those remaining at home in the enlisted reserve corps or on the teaching staffs should not utilize the summer months to good advantage. The Council, however, is not unanimously in favor of the continuous session, since one member believes that the speed of production gained would not compensate for the loss of the thoroughness in teaching and the drain on the students' health. It is stated that at McGill and Toronto universities in Canada the system has been abandoned excepting for the last year students.

I have purposely quoted this report in full for future reference.

Prof. Arthur Dean Bevan, president of the American Medical Association, in his address,* says, in regard to the training of nurses:

One of the serious problems now confronting us is the securing of the necessary number of women nurses for our army and navy hospitals. We shall need from 25,000 to 40,000 women nurses. These cannot be secured from

* *Journ. Amer. Med. Association*, June 15, 1918, p. 1849.

* *Ibid.*, p. 1808.

the trained and registered nurses of the country and leave a sufficient number of nurses to care for our civilian population. It requires three years of training in times of peace to educate a nurse. But we must remember that in peace times it requires a four years' training at West Point and Annapolis to make an officer of the army or navy. In the emergency of this war we are developing splendid officers from well-educated, capable men taken from civil life, by intensive short three months' courses in our officers' training camps. The same plan should be adopted in securing the necessary nurses.

There are thousands of well-educated, capable young women in this country who are not only willing but anxious to offer their services to the country. Nurses' training camps and training schools can be developed in our army and navy cantonments, where, with an intensive three months' training, these young women can be developed into most useful war nurses, and meet the needs of the Government. The Surgeon-general of the army has already taken steps to encourage these nurses' training schools.

The report of the Council on Medical Education, because of the adverse opinion of one member, did not affect the views of Surgeon-general Gorgas. It will be observed on page 1950,* under the heading "Memorandum for the Surgeon-general of the United States Army," that he called a meeting of the Advisory Committee on Medical Schools on June 11th, and devised a plan by which the best medical schools in the country could carry out the views suggested in the report of the Council on Medical Education. It will be seen, therefore, that the most difficult situations may be overcome when there is a disposition to correct faulty methods or to improve old methods of teaching.

In the evolution of dental training for our students from a two-year course to a three- and then to a four-year course, I have from time to time advocated the utilization of the summer months to reduce the length of time for study and graduation. In these strenuous times I am again offering suggestions whereby the student may attain all that is re-

quired of him and at the same time curtail the length of the curriculum.

The teaching of dentistry proper has no analogue in any other department of science. In all other departments of science taught in schools and colleges, the mental capacity of the student is frequently strained before the end of the term, and brain-fag is likely to occur when pushed to the utmost, as noticed in the report of the Council on Medical Education.

The dental curriculum in our colleges is divided into two distinct departments. It is composed of part mental and part physical training. The principal part of the student's course which qualifies him for graduation is made up of mechanics, where brain strenuousness is not required. He naturally exerts the greater part of his energies in this direction at the expense of the mental and theoretical. The question naturally asked is, Why should not dental schools follow the medical, by adopting a three- or perhaps a two-term yearly course, thereby curtailing the time of the dental students? Surely this can be accomplished to the advantage of both the students and the colleges without detriment to either. The winter course could be utilized for the mental and theoretical, and the summer for the mechanical and practical work. By this method, a year and perhaps more time could be saved.

In other walks of life, such as bookkeeping, typewriting, proofreading, money-counting in the treasury department of the Government, in machine shops, in foundries, in boiler shops, in jewelry manufactories and shops, in sweatshops, and in fact in almost all of the avocations of life, men and women beyond the middle age of life toil from fifty to fifty-two weeks throughout the year, confined in the same close room all day and almost all the time in the same position, usually with artificial lights. Those who do obtain a vacation are satisfied, as a rule, with two weeks. Surely two or three weeks' vacation is all that a young man or woman requires each year while studying for the dental degree.

* *Ibid.*, June 22, 1918.

Brain-fag from overwork due to constant use of one set of brain-cells is overcome by professional men by substituting light fiction reading. By this substitution literary men and scientists may and do live many years without feeling fatigued in the least. The dental student, therefore, has the advantage over all other students in that he can substitute for his winter course of mental training a summer course of mechanics.

A student entering college is always

desirous of finishing his studies as soon as possible, so that he may enter his profession and become independent of his family. By the present methods of college teaching he is losing a year's time in the four-year course. This, with the cost of tuition and the expense of office equipment, is quite a drain upon any young man entering upon a professional career.

31 N. STATE ST.

Cancer of the Oral Cavity.

By L. DUNCAN BULKLEY, A.M., M.D., New York, N. Y.,

SENIOR PHYSICIAN TO THE NEW YORK SKIN AND CANCER HOSPITAL, NEW YORK CITY.

THE dentist has a great responsibility concerning cancer of the oral cavity, for he of all others is most likely to see the beginnings of the disease. Every malignant lesion has its origin in an often insignificant focus, and if properly treated at a very early stage the prospects of a cure are immeasurably greater, or rather, the prospects of an unfavorable result are materially lessened; for the end results of cancer of the oral cavity are thus far very discouraging, except in regard to cancer of the lip when taken very early.

During the year 1914 there were in the registration area of the United States 2270 deaths from cancer of the oral cavity, or 4.3 per cent. of the 52,420 deaths from cancer in general, or 3.4 persons per 100,000 living. Of these, 376 were from cancer of the lip, 614 of the tongue, 230 recorded as of the mouth, 851 of the jaw, and 199 others of this class. Of these 2270 cases of cancer of the oral cavity 1878 were in males and 392 in females, 82.75 and 17.25 per cent. respectively, the males being sufferers almost five times more frequently than the females.

Malignant disease is very rare in this locality before the age of twenty-five, there being only 40 deaths reported; sarcoma is the form most frequently found in the young. After the age of twenty-five the number of deaths rises steadily, reaching a maximum of 307 between sixty-five and sixty-nine years of age, and 299 from seventy to seventy-four years.

It may be interesting to note that in the United States registration area deaths from cancer of the oral cavity have increased more than those from the disease in any other locality. Thus in 1900 the deaths were 1.6 per 100,000 population, and in 1914 they were 3.4, more than double, whereas the general increase of cancer mortality during this period was from 63 to 79.4 per 100,000, or 26.6 per cent.

In regard to the early recognition of cancer in many localities it is difficult to speak certainly and concisely, but in cancer of the oral cavity there is less reasonable excuse, and the dentist will often be the first medical man who can give the warning. And this warning should be positive and clear, for even the life of the patient may be dependent upon it.

A lesion which may seem trifling at first may be the beginning of a most serious trouble, quite uncontrollable in later stages. When in doubt as to the nature of the local lesion skilled counsel should be sought.

This is all the more important when it is remembered that it is universally acknowledged that about 90 per cent. of all those once affected with cancer in general, in all localities combined, ultimately die of the disease. Also that from 1910 to 1916 the general death-rate from cancer has risen from 63 to 81.8 per 100,000 of the population, or 29.84 per cent., in spite of intelligent and active surgical treatment.

IMPORTANCE OF ACCURATE DIFFERENTIAL DIAGNOSIS BETWEEN CANCER AND OTHER DISEASES OF THE ORAL CAVITY.

One can readily see, therefore, the great importance of an early and accurate differential diagnosis between cancer and the various disease conditions which may appear in the oral cavity; some of these we will mention briefly, as time would not allow any attempt to detail fully the diagnostic features, which are well given in the textbooks.

(1) *Syphilis*. Next to simple aphthous sores, syphilis is probably the most frequent and important cause of oral lesions to be differentiated from cancer. These are sometimes difficult of absolute diagnosis, though the Wassermann test may often be of great help. Syphilis appears in the mouth as the primary lesion or chancre, mucous patches, and late, gummy lesions. The primary lesion of syphilis or chancre occurs in the mouth often enough to make it an object of interest in this connection, and should never be forgotten. In a study of extra-genital chancre* I was able to collect from literature accounts of 9058 cases, of which 1504 were within the oral cavity and 1810 on the lips, making a total of 3314 chancres in this region, or 36.6 per cent. of all cases. Of the oral cases

there were 734 recorded as in the buccal cavity, 157 on the tongue, 307 on the tonsils, 264 in the throat, and 42 on the gums, a considerable number of which were attributed to infection through dental work or instruments.

Mucous patches are often with difficulty distinguished from aphthous stomatitis or canker sores, but should never be confounded with cancer, although the latter may occasionally develop on them.

The late gummy lesions of syphilis, especially on the tongue, often resemble cancer very closely, and indeed may be the starting-point of true cancer.

(2) *Aphthous stomatitis* or canker sores are generally easily recognized, but if one or more of them should persist it is always well to consider the possibility of its being the beginning of a true cancer.

(3) *Leucoplakia*, generally caused by tobacco, is often spoken of as a precursor of cancer, but among scores or hundreds of instances of leucoplakia seen I do not recall a single instance in which cancer developed. It is quite possible, however, by bad treatment, as by "touching it up" with nitrate of silver, to goad this and other previously innocent lesions to take on malignant action, and I have seen cancer which had developed on leucoplakia before coming under my observation. Any ulcerative changes on a leucoplakia should always be regarded seriously, as possibly an early cancerous development.

(4) *Simple ulceration of the tongue* or buccal cavity should always receive careful attention, and if persistent should be regarded with suspicion as a probable antecedent of cancer. Broken, rough, or decayed teeth are the chief source of these ulcerations, and tobacco often plays a very important part, as may be judged by the fact that cancerous lesions in the mouth are almost five times as frequent in the male as in the female. On the other hand, where the practice of chewing a mass composed of betel leaves, tobacco, and lime is common, as in the East, these malignant lesions are very common in the mouth of both sexes.

(5) *Tubercular lesions*, or lupus, oc-

* Bulkley, "Syphilis in the Innocent," New York, 1894.

asionally resemble cancer in the oral cavity, but these are rare.

On the lip the dentist may frequently see lesions which are precursors of cancer, and may be the first to give warning. Prolonged fissure of the lip is always significant, and cannot be too carefully guarded. Cancer also follows irritation by pipes and even tobacco used in any form, and a persistent ulceration after a "fever blister" should always be regarded seriously.

It is difficult to describe briefly the characteristics of cancer of the oral cavity. In advanced cases with prolonged ulceration and hard, everted edges, profuse discharge, and much pain, the diagnosis is of course simple. But the very early cases, where the beginning cancerous lesion is only a small rebellious ulceration, with little if any hardness, and very little pain, the certain diagnosis is not easy, even for an expert. And yet these are the cases in which the dentist can render the best service by giving an early warning, which if heeded properly may save untold misery.

The main exciting causes of oral cancer, as has been intimated, are irritating, rough, broken, or decayed teeth, and also ill-fitting plates, etc., together with tobacco, syphilis, and alcohol. But as these causes are continually operating in millions of persons, while so relatively few develop cancer, there must be some predisposing cause which renders the local or exciting cause operative. This constitutional cause I have endeavored to demonstrate elsewhere,* and need not be dwelt on now, other than to state that the dietary and medical treatment of cancer offers the prospect of far better

results than have thus far been obtained with the knife. The danger of neglect or even trifling with the beginnings of cancer can hardly be emphasized strongly enough, for it is in its earliest manifestations that this dire disease can be most readily controlled and even removed by medical treatment.

NITRATE OF SILVER CONTRA-INDICATED IN THE TREATMENT OF CANCER.

I have already alluded to the harm that may come to originally innocent mouth lesions by the injudicious application of nitrate of silver, as was formerly so commonly done, but I cannot refrain from again mentioning and emphasizing the matter. It is a very dangerous, and one may almost say a criminal procedure. Its action is far too light and superficial to destroy a malignant growth, and the stimulating effect of nitrate of silver may cause a benign lesion to take on a malignant character.

All stimulation should be strictly avoided, and all sources of irritation removed. Cancer is known to develop under conditions of acidity, as in the stomach, large intestines, and urinary bladder, and the saliva is generally found to be acid in these cases. Only mild alkaline mouth-washes should be employed, and of these sodium bicarbonate is about the best, used freely before and after eating or oftener.

It is impossible in a single brief article to cover all the ground that might be desired, and I must content myself if I have directed serious attention to the share which dentists may have in lessening the increasing morbidity and mortality of what is so often a distressing disease, namely, cancer of the oral cavity.

The First Line Trench in Dentistry.

By M. EVANGELINE JORDON, D.D.S., Los Angeles, Cal.

(Read before the Southern California Dental Association, May 28, 1918.)

A GREATER appreciation of the jealous conservation of every minute of time devoted to the program is one of the lessons I have learned from being upon the board of directors of a large club, so I esteem it a great honor to be given a place among your speakers.

For two reasons I am glad to bring my simple message to you. First, because this is a time when scientific prevention is being studied in every detail; and second, because this is children's year. President Wilson, writing to the Secretary of Labor, says: "Next to the duty of doing everything possible for soldiers at the front, there could be, it seems to me, no more patriotic duty than that of protecting the children, who constitute one-third of the population, and I heartily approve the plan for making the second year of the war one of united activity on behalf of children, and in that sense a children's year. I trust that the work may so successfully develop as to set up certain irreducible minimum standards for health, education, and work of the American child."

The draft examinations of our first year of war have focused the attention of the public upon the condition of the teeth of our young men. It is too soon to obtain many statistics in regard to these conditions, but I shall mention a few.

Quoting from a paper by Dr. Adelaide Brown of San Francisco, read at the State Federation of Women's Clubs, in Oakland: "In one group of 8000 men, 480 were rejected because they did not come up to the standard of two pairs of

opposing grinders, bicuspid included with molars."

Dr. Costello, of the Medical Reserve Corps of the U. S. Navy, says: "Twenty-seven per cent. of the rejections at the recruiting stations are for teeth which have been neglected until their condition is beyond repair. The minimum requirements of twenty sound teeth, of which there must be four opposing molars and four opposing incisors, with crown and bridge work counting as sound, is fair, and a man's mouth could hardly be considered in good condition without conforming to this requirement."

In Italy 50,000 soldiers have been incapacitated because of defective teeth.

We have no reliable statistics as to Germany, but we know that forty years ago, in preparation for "the day," she began to perform dentistry in the schools. You remember that quite a number of years ago Dr. Moore of Santa Barbara told us that, the clinic results proving unsatisfactory, the German children were being given prophylaxis in the kindergarten.

All this has brought us to realize the urgent necessity of prevention, and such a prevention that we shall not bear the stigma of having a large percentage of our picked population fail in the military examinations because of having defective teeth at an age when they should present almost perfect mouths.

In justice to the dental profession I must say that for years this has been recognized, but the politicians who have controlled our state revenues have been

too shortsighted to make adequate provision for preventive measures, and it still remains the work of the dental profession to build up a public opinion which will force such protection.

Caries of the teeth is distinctly a disease of childhood, and must be combated just as originally smallpox was, and its extermination, while not easy, is just as possible. It is simply a question of education, with every practicing dentist a professor of instruction to his entire *clientèle*.

The causes of early caries are several, among which prenatal conditions play a part. Serious illnesses or shocks to the system of the mother during the nine months of pregnancy may be so registered upon the system of the child that both physically and mentally it may be subnormal. After birth the child who is nursed has twice as good a chance for better dentures as well as better-shaped jaws. The largest percentage of children who need dental care have been bottle-fed.

One of the most frequent mistakes of the past was made at the time of changing from liquid to solid food, because the parent gave semisolids which adhere to the teeth, instead of hard foods which leave the teeth polished and clean. The average American child was, and is, given too large a percentage of carbohydrates in its diet.

To quote Luther Burbank in his work "The Training of the Human Plant" (New Century Co., publisher, 1913), "Growing children need a greater proportion of body-building foods, such as lean meats, fish, milk, some vegetables, and fruits. They are often fed too great a proportion of sweet and starchy foods. A certain proportion of these are absolutely necessary, but we all know the 'starch babies' by their pale, fat, flabby, characterless faces, lusterless eyes, and general lack of vitality." Had he been a dentist he would have added, "and mouths with coated tongues and ropy saliva." He goes on to say: "Less starchy foods and more fresh meats, with eggs, milk, some vegetables and fruits, will give more vitality, a better growth,

greater intelligence, better health, and a better constitution, notwithstanding the belief of some of my vegetarian friends to the contrary."

Another mistake often made is to let a child begin breakfast with grapefruit or other acids, followed by a starchy cereal, such as cream of wheat, smothered in cream and sugar. Such children always improve in health when put upon a sensible diet. Mastication plays an important part in the digestive process, and children who have mushes and liquids with their meals seldom learn to masticate—a habit that must be acquired in childhood. Bolting of food has many serious consequences, but in a short paper such as this I shall mention only one, pyorrhea. I have yet to see anyone, who does not exercise his teeth and gums, who has passed middle life without having swollen and bleeding gums.

Adenoids and enlarged tonsils also play their part in caries of the teeth.

The last to be mentioned of the causes of caries is the neglect of the care of the teeth at home. It is surprising that in a day when so much is said of this, there should still be children without toothbrushes, but many young children are brought to me who have never had one.

IMPORTANCE OF SAVING THE FIRST PERMANENT MOLAR.

When caries appears in the mouth of a child two or three years of age, unless careful repair work is done at once and the cause is discovered and removed, the first permanent molar when it appears, at six or seven years of age, has not a chance to survive.

Those of you who study radiographs know how futile it is to expect a perfect occlusion with these cornerstones of the arch missing, and I, for one, can speak feelingly of the suffering due to malocclusion from losing my first molars in my twelfth year.

One cannot say too much of the first molar, the most valuable tooth in the mouth—"the first line trench," to use a war term. Its position makes its loss

one never to be repaired. Anyone who studies the science of occlusion will readily tell you that the first molars are the most valuable teeth, because they are in position during the six years when the deciduous teeth are exfoliating and the permanent teeth are taking their places in the growing arches.

Because it is often mistaken for a deciduous tooth it is neglected; for, alas, there are still dentists who say of deciduous teeth, "Do not bother with them, they will soon be lost," without stopping to explain that a carious deciduous molar does not require the six years it will approximate the permanent molar to be destroyed. One year will be sufficient for that—for destruction is always more rapid than prevention.

You ask the remedy. And I answer: Education! Already it has been started in the schools, first by the clinic, which brought relief to the suffering children and then increased health and vitality. This last year Dr. Proctor has been doing some work by lecture and tooth-brush drill in our city schools, but it is a task of such magnitude that each one of the profession must lend a hand, and make it his business to tell one or more people each day the need of care of the adolescent mouth while he is repairing the losses of an adult mouth. The most beneficial treatment is to begin monthly prophylaxis not later than the fifth year. This treatment cannot be too carefully emphasized.

The preponderance of soft carbohydrate foods in the diet is one of the causes of so many children entering the kindergarten with their teeth broken down to the gums and with small, undersized jaws. One of our responsibilities is spreading the knowledge that no demineralized white bread or crackers should ever be given to a child under five years of age. We not only need all the lime salts contained in dark breads to build the teeth and bones, but we need exercise to develop the jaws. Children who eat tough bran bread made into toast instead of mush, and who do not drink while eating, usually get the proper development of the jaws.

Mouth hygiene, to be effective, must be begun as the child enters school, not left until the first permanent molar is breaking down.

Unless you have examined the mouths of the children in a kindergarten you have no idea how many of them have from one to six or seven, and I have treated as many as ten, teeth with abscesses and with the gums covered with spongy fistulous openings. Under modern conditions of bottle-fed babies, impure foods, and crowded city life, a large number of children begin to need dental attention in the second and third years, and often some of the teeth are lost by the fourth year.

Anyone who is not familiar with such cases can readily imagine the great strain upon the system due to the septicemia that quickly follows the death of one or more pulps in a child's mouth. I leave you to picture the condition of such a child when it reaches the age to enter kindergarten, if it lives so long: Sickly — anemic — irritable — stupid! Every child compelled by the law to attend school has the *right* to be protected from the spread of disease through the germ-laden breaths of the filthy mouths of such children.

BEST METHOD OF CARING FOR THE TEETH OF SCHOOL CHILDREN.

In working for very young children I have found that if the teeth are polished once a month and given reasonable care at home, no cavities will form.

In an endeavor to find the most economical way in which to care for the teeth of school children, I have come to the conclusion that the following plan will produce the best results, because the work is begun before or at about the time of the eruption of the first permanent molar, which under present conditions is more often lost than any other tooth in the mouth—a loss irreparable to the whole system of the child:

(1) Have the teeth of all children filled, when necessary, before they enter the kindergarten.

(2) Have a daily morning cleaning of

the teeth as part of the exercises in the kindergarten.

(3) Mark children upon their oral hygiene just as upon reading or spelling.

(4) Arrange games that will develop strong, correctly shaped jaws, such as lifting weights with the teeth, or rapid running with tightly closed lips.

(5) Give all the children in the kindergarten and the first grade monthly prophylaxis.

This last undertaking sounds formidable, but it could easily be managed at a small expense by having an auto van fitted as a dental office, to carry four dental chairs and an office desk. The force could consist of one dentist with four dental nurses and an assistant to sterilize instruments. The van could be moved from school to school, the work in each school requiring part of a day only.

The electricity for the dental engines and sterilizer could be furnished by the engine of the van. Water could be connected at any hydrant, and the waste pipe could be connected with the sewer. The dentist in charge could oversee the work, mark the school cards, send any unusual cases to the established dental infirmary, and lecture at mothers' meetings.

The result of such work would be magical. Epidemics of colds, measles, whooping-cough, etc., would be almost unknown, and the amount of school work accomplished in each room would be greatly increased. This would be one of the best ways to fight tuberculosis.

The final argument in favor of such a method is that the school should teach the children the most valuable lessons in life—physical development and keeping the gateway to the body clean—by repeated lessons, just as it teaches them to read.

The Southern California Dental Association has been trying to educate the people since 1901. The question is, Have we tried hard enough and in the right way? Are there more perfect first molars or not? Also, what is being done to banish children's diseases? To be sure, when a child has measles or whooping-cough he is sent home, but is not often kept in quarantine; so he plays

around the neighborhood and all the children under school age in the neighborhood may be exposed. This would not be so serious a matter if only the child in school were affected, but it is the child under school age, the baby brother of six months (who is on the bottle), or the little sister of two years, either of whom may not possess great resistance to disease. In such a case the fever may run such a course that malnutrition with lowered vitality will arrest the developing permanent teeth. Hypoplasia of the first permanent molar often results, decreasing its value fifty per cent.

With healthy children, a monthly polishing of the teeth and proper care at home is sufficient, but since many children are below normal in health, it requires watchful care to save the first molar. In such cases, when the tooth first appears the fissures may be polished with an orange-wood stick and pumice, then dried with alcohol, and cement flowed in, filling it nearly even with the cusps. When the occluding tooth comes into position, this will gradually wear down. Later, if the fissures darken and any softening is found, remove all caries and extend the cavity with a shallow undercut to the ends of the fissures and fill with copper amalgam. I believe there is no preventive measure of greater value than these copper amalgam fillings in unhealthy mouths.

You all know my views with regard to silver amalgam fillings in the mouths of youth. There is only one place in which I use them, and that is in the mesial cavity of the first molar before the bicuspid comes into position, and I am not sure that they are satisfactory there.

The perfecters of the gold inlay have done great service in giving us an easy and a nearly perfect way of repairing the first molar, taking into consideration the fact that no repair can be as satisfactory as healthy tooth structure. However, in its use great care must be taken in preserving correct points of contact.

When the pulp of the tooth is involved, one must be most conservative and exhaust every resource to keep the pulp alive until root formation is completed.

Here the X-ray is our valuable aid in watching the progress of the treatment. Every ounce of skill we possess should be marshaled to our assistance in the care of such cases. Every rule and every preventive detail of sterilization should be followed in filling the root-canals.

But above and beyond all, let us build up a plan to prevent this loss of the first molar in youth, and save the future dentist the intricate and nerve-racking task of saving these forlorn hopes.

Let us do our part in this children's year by teaching every mother in America to watch for the arrival of the first molar after a child is five years of age,

and to have the mouth in proper array for this the most-valued tooth—our *first line trench* in dentistry!

What is to hinder the dentists of America from adopting the most successful movement of the day? Why cannot we, too, start a *drive*—a drive to save the first molar, the innumerable first molars? Why cannot the dental associations ask the many "children's year" committees to devote at least one week this fall to the education of the mothers of America, to emphasize the value of, and teach them to save, the first permanent molar!

1123 MARSH-STRONG BLDG.

The Pathogenesis and Treatment of Pyorrhea Alveolaris.

By B. KRITCHEVSKY and P. SÉGUIN,

OF THE PASTEUR INSTITUTE.

(Translated from *la Presse Médicale*, Paris, May 13, 1918.)

THE medical profession has long ignored the importance of pyorrhea alveolaris in its relation to systemic conditions. However, in the course of the last few years numerous secondary complications have been attributed to it, such as arthritis, myositis, endocarditis, neuritis, and even gastric ulcer and appendicitis. In the presence of these infectious conditions, the medical practitioner is under obligation to examine the state of the oral cavity, if he fails to find elsewhere the cause of the disease.

(I) The pathogenesis of pyorrhea is still under discussion. This disease has been attributed to the oral representatives of the pneumococcus-streptococcus group, to the endamoeba gingivalis, or to various other organisms. Corresponding with each of these conceptions, there has been advocated a particular treatment.

The oral pneumococci and streptococci have been incriminated by a number of authors, certain of whom have sought to contend with these germs by vaccines,

either autogenous vaccines prepared from one or several species or stock vaccines. Vaccines in which the organisms have been killed by heat or sensitized vaccines or iodized vaccines have been employed, and the results obtained in this way have in general been satisfactory. This is not surprising, because even if the organisms against which this form of treatment was directed are not the actual etiologic factors in pyorrhea, they nevertheless are not inoffensive, and they contribute toward maintaining the suppuration.

The amœbic theory gained some wide degree of popularity, and accordingly attempts have been made to treat the affection by injections of emetin, but recent work has shown that endamoeba gingivalis cannot be considered as the causative agent in pyorrhea. As far as our own experience goes, in the numerous cases which have been studied, we have never with any constancy demonstrated the presence of amœbæ.

Let us add finally that quite recently Mendel⁽¹⁾ has isolated from cases of pyorrhea alveolaris various bacteria, with which he was able to reproduce in animals lesions with symptoms resembling those of the human disease.

Whatever be the cause of pyorrhea and the general treatment followed, there is nevertheless one point upon which all specialists are in accord, namely, the absolute necessity of a well-performed and persevering local treatment. It is important to remove by most careful scaling all of the deposits which have formed upon the roots of the teeth. This material, by its mere presence, irritates the gums and denudes the teeth, impinges upon the periodontal ligament, and breaks up the intimate union of the root with the alveolus. Tartar plays in the genesis and in the recurrence of the affection an etiologic rôle of the first order, and therefore it must be unconditionally removed.

(II) In May and then in September of 1915 there appeared the work of Barton L. Wright⁽²⁾, who detailed the treatment of pyorrhea alveolaris by intra-muscular injection of succinimid of mercury. The dose employed was from 12 to 26 mg. for women and 65 mg. for men. In the cases of 60 patients thus treated, the pyorrhea was cured, and with it the secondary intercurrent infections, such as arthritis, etc. The author thought that the mercury acted as a powerful antiseptic, destroying the oral pneumococci and streptococci.

We have employed this method, as well as the others before mentioned, and have been struck by the good results which often are secured. Following the mercurial treatment, the pyorrhea was clinically improved, the secretions dried up or were greatly decreased, and the gums once more became firm.

If the discharge be examined before and after treatment, one fact stands out prominently, i.e. in cases not yet treated, besides a great variety of diverse micro-organisms, there swarm innumerable spirochætæ. As a consequence of the mercurial treatment, in the majority of cases, these spirochætæ almost completely disappear from the secretions.

These facts led us to think that the cause of pyorrhea alveolaris might be primarily due to the local abundance of one or several species of oral spirochætæ, with which there were secondarily associated various other microbes. The disease would then be in our estimation a spirochaetosis, complicated by diverse microbial associations (symbioses).

Smear of gingival exudate from an untreated case of pyorrhea alveolaris. Stained by the ammoniacal silver nitrate method of Fontana-Tribondeau. (Note predominance of spirochætæ and their great diversity of forms.) Magn. Zeiss obj. 1/12, oc. 6.

From this standpoint it is interesting to note that in 1912 Noguchi⁽³⁾ isolated from pyorrhetic pus a treponema, *T. mucosum*, to which he attributed a certain rôle in the production of the fetidity of the pus.

We then conceived the idea of trying in the treatment of pyorrhea alveolaris the spirochaeticidal medicaments, which are more energetic than the salts of mercury, such as the arsenical compounds "606" and "914." Huchard had already employed such treatment in Vincent's angina. Nevertheless, as these medicaments have quite numerous contra-indications and require a somewhat delicate manipulation in administering, we had hitherto hesitated to resort to intravenous injections.

Quite recently we came upon the work

of Kolle⁽⁴⁾, who claims to have cured 90 cases of pyorrhea by intravenous injections of neosalvarsan (maximum dose of 30 centigrams), and this in the absence of any local treatment. After three injections at most, the most obstinate cases were cured. In Kolle's opinion, the causative agent is a special spirochæte, large, with wide curves in its spiral, morphologically greatly resembling the spirochæte of recurrent (relapsing) fever. This organism disappeared completely from the gingival exudate after the arsenical treatment.

Desirous of controlling Kolle's observations, which confirmed our facts and corroborated our hypotheses, we consulted with Professor Jeanselme, in whose service there are daily given a large number of injections of neosalvarsan. Professor Jeanselme very kindly authorized us to make the needful observations upon the patients of his service, and we are happy to acknowledge here our gratitude to him.

In order to study the action of the specific treatment, and in particular the action of neosalvarsan upon the oral spirochætes, we worked with samples of the gingival exudate in a large number of patients who were undergoing treatment, 244 subjects being thus examined. The exudate was taken from many places in a pipet, diluted with water and spread upon a slide, then stained with Tribondeau's methylene eosinate.

Of the 244 patients, some (110) had

never been treated; others (134) had on the contrary already undergone specific treatment—mercury in one or another of its various forms, injections of "606," or of neosalvarsan. Of these 244, 43 were affected with advanced pyorrhea; 62 presented only the first signs of this disease, a large accumulation of tartar and slight recession of the gums; in 139 the gums were normal.

We have classified the results of our observations in Table I.

The following comments are suggested by this tabulation:

(A) In three-fourths of the cases of pyorrhea spirochæte are abundant. If the patients have not previously undergone any specific treatment, there are in almost all cases (24 as against 2) an abundance of spirochæte. The cases of pyorrhea in which there are only a few or even none at all of these organisms (11) are particularly to be seen in individuals already treated.

When pyorrhea is in its initial stages, spirochæte are found in half the cases (31 out of 62). When the mouth is healthy, the spirochæte are rare or absent in about three-fourths of the cases (101 out of 139).

(B) In half of the 110 cases never having had specific treatment, spirochæte are abundantly encountered in the gingival exudate.

Out of the 143 subjects already treated by specific medicaments (Hg (mercury), "606," "914"), spirochæte

TABLE I.—FREQUENCY OF SPIROCHÆTE IN THE GINGIVAL SECRETIONS OF PATIENTS, SOME OF WHOM HAD SUBMITTED TO SPECIFIC (ANTI-SYPHILITIC) TREATMENT, OTHERS NOT.

Spirochæte.

| | ABUNDANT. | | | RARE OR ABSENT. | | |
|-----------------------------------|--------------------|----------------|--------|--------------------|----------------|--------|
| | Cases not treated. | Cases treated. | Total. | Cases not treated. | Cases treated. | Total. |
| With pyorrhea, 43 cases | 24 | 8 | 32 | 2 | 9 | 11 |
| Mild pyorrhea, 62 cases | 12 | 19 | 31 | 10 | 21 | 31 |
| No pyorrhea, 139 cases | 19 | 19 | 38 | 43 | 58 | 101 |
| Total, 244 | 55 | 46 | 101 | 55 | 88 | 143 |

are found only in a third of the cases.

Let us now see the action of neosalvarsan treatment upon the spirochætæ of the mouth. We have followed the effects of repeated injections of neosalvarsan in the cases of 100 patients, who have received from 6 to 10 injections of 10 to 60 centigrams.

Of these 100 patients, 42 possessed, before beginning the treatment, many spirochætæ in their gingival exudate. The following tabulation gives a *résumé* of results observed:

TABLE II.—EFFECT OF REPEATED INTRAVENOUS INJECTIONS OF NEOSALVARSAN UPON THE SPIROCHÆTÆ OF THE GINGIVAL EXUDATE.

| <i>Spirochætæ.</i> | | Disappeared. | Always plentiful. |
|---------------------|----|--------------|-------------------|
| Marked pyorrhea ... | 13 | 7 | 6 |
| Mild pyorrhea | 13 | 11 | 2 |
| No pyorrhea | 16 | 11 | 5 |
| Total | 42 | 29 | 13 |

Thus the treatment resulted in the disappearance of the spirochætæ in 29 cases (about 70 per cent.); on the contrary, in 13 cases the action of the neosalvarsan was not appreciable.

The cases of pyorrhea were always clinically ameliorated, and in more than half of them the spirochætæ disappeared from the exudate. It must be noted that this disappearance is never complete; the organisms remaining are represented by the rarer forms, which are few in number, thickened, swollen, and inactive.

Without being as schematic as those of Kolle, the results which we have obtained are nevertheless demonstrative. And this is the more significant, as none of these patients had undergone local treatment. The irritating tartar had been left intact. In some cases the medicament could not reach the spirochætæ, which were hidden in almost completely closed pockets.

Finally, besides these cases treated by intravenous injections of "914," we have cared for some patients affected with pyorrhea by local instillations of neosalvarsan in solution or by application of

the medicament in powder form into the pyorrhætic pockets. The results, both from the viewpoint of clinical improvement and from that of the rapid disappearance of the spirochætæ, have invariably been remarkable.

(III) How should pyorrhea be treated? The treatment should be both general and local.

(1) The general treatment consists of intravenous injections of neosalvarsan (10 to 30 centigrams). If this be contraindicated, or if particularly technical difficulties present, intramuscular injections of succinimid of mercury may be substituted therefor.

(2) The local treatment is just as necessary. If the tooth be very loose and its alveolus destroyed (the radiograph will indicate this), it is useless to expect the tooth to again become firm, and the best thing to do is to extract it.

If the alveolus be only partially involved, a most careful scaling and even polishing of the root should be practiced. To aid in the disintegration of the calculus, it is advisable to use fluorin salts to render it more friable.

Finally, in addition to this mechanical treatment, the spirochætæ may be directly attacked by instilling active medicaments (neosalvarsan in solution or powder) into the pyorrhætic pockets.

But this chemotherapy does not establish immunity. Relapses and returns of the infection are always to be feared. The sole method of preventing them is to impress upon the patient the necessity for a thorough and unrelenting course of oral hygiene. The patient should learn to clean his teeth with the greatest care, or in default of this, to have frequent recourse to the attentions of a specialist.

Success in Oral Restoration: What are the Fundamental Principles upon Which It Must be Based?*

By JAS. KENDALL BURGESS, D.D.S., New York, N. Y.

(I.)

(Read before the Northern District Dental Society, Bronx and Westchester Counties, N. Y., May 23, 1918.)

IN entering upon a consideration of our subject it seems wise to determine just what is meant by the term "oral restoration," and what is intended to be accomplished by such an operation.

Perhaps the first word that should be said is that, in a strict sense, there is no such thing as restoration. The best we can hope to achieve is not restoration but substitution; but we use the word "restoration" because it is the ideal—even though, like all ideals, unattainable—toward which we direct our efforts, and because it conveys a more pleasing picture to the mind.

Lest we forget, and in order that we may get a wider and clearer perspective, let us come back for the moment to the A B C, as it were, and consider briefly the normal oral cavity and its contents—the departure from which normality makes restoration necessary—with some, at least, of its relations and functions.

Nature has provided the human organism with a marvelously constructed and co-ordinated apparatus which we know collectively as the denture. This is divided into upper and lower halves, and each half is subdivided into numerous segments or units or teeth varying in size and shape according to location and the particular service for which nature intended them. Each tooth comprises an exposed or visible portion—the crown—

and one or more submerged subdivisions or roots by means of which it is anchored in position, and every tooth is composed of five tissues, viz, enamel, dentin, cementum, the pulp, and the periodental membrane. Surrounding each root is a bony wall, forming a receptacle or socket which is called the alveolus, and this in turn is part of the mandible or maxilla, as the case may be. Overlying these bony structures or jaws and coming in contact with the teeth at their necks where root and crown meet is the dense vascular tissue—the gum.

The gum conveys nourishment and affords protection to the bony structures, and the bone in turn provides anchorage for the teeth, and sustains the burden and the stress of the service to which they are put. The tough, fibrous periodental membrane serves as the medium of union between the tooth and its supporting alveolus, and cushions the bone from the direct force or shock of the impact produced in the performance of its mechanical function. The cementum or covering to the root affords a suitable material for the embedding and attachment of the fibers of the periodental membrane just described.

The dentin gives bulk, general conformation and color to the tooth, houses the pulp and supports the enamel; and the enamel, largely a mineral substance,

* [This is the first paper of a series to be presented by the author on the fundamental principles of oral restoration.—Ed.]

gives final form and shade to the crown of the tooth, and constitutes nature's protecting covering to the more highly organized and sensitive interior tissues, standing as it does between them and frictional wear and tear, thermal changes, the products of fermentation, and all external influences to which the teeth are subjected. The pulp is the supply conduit that forms the vital union between the tooth and the vascular and nutrient centers of the organism. The function of the periodental membrane is more particularly that of a local mechanical bond of union between the tooth and its bony anchorage, while the pulp constitutes the means of communication that brings the tooth into relation with the great outlying influences in the body, giving it a larger community interest and a more important status in the society of members of the human body, incidentally greatly increasing its responsibility to these other members of this society for its good behavior.

The individual teeth of each half of the denture bear a relation to their fellows of close contact on their proximal sides for mutual support, and for mechanical protection to the supporting tissues which form thin partitions between their necks. The opposing halves of the denture bear to each other a relation in which the free ends of the lower half come into contact with those of the upper half, completing an arrangement which we describe as occlusion. The functions of the denture as a whole which here concern us most are the esthetic, for which the anterior teeth are more particularly responsible, and the masticatory—or first aid to digestion, performed principally by the posteriors and resulting from a triturating or grinding movement of the lower half of the denture against the upper, operated by a series of tissues or muscles in their function of alternate relaxation and contraction which we describe as muscular action.

This is a brief analysis of the divisions and subdivisions, with some of their relations and the functions which concern us most, of the apparatus with which we have to deal. These facts are so elemen-

tal and so obvious that they ought scarcely need repeating. But I have done so for two reasons: First, because a recital of them is necessary to the development of my thesis, and second, because their very familiarity breeds a spirit of forgetfulness if not of contempt, and there is danger that we lose sight of their significance and their importance, as some indeed seem prone to do. It is intended to refresh our memories and recall more sharply to our attention the correlation and interdependence of these organs and tissues, and their relation and importance to the rest of the organism.

It is the impaired or lost units of this denture for which, when accident or morbid process has wrought its havoc, we are called upon to make substitution, and our effort and its results are what we characterize as "oral restoration."

The question to which we seek the answer is, "What constitutes success as applied to our undertaking, and how shall we attain it?" At first thought the answer seems simple enough. It is not so clear, however, but that there is room for confusion of ideas and errors of judgment. This I believe is due to our failure to discover and apply the bedrock principles which must underlie our efforts. We discuss technique, quibble over its details; lose ourselves in its intricacies and, enticed to ridiculous extremes by the almost hypnotic influence of its mechanical fascinations, we make of it, all too often, the end instead of the means by which we attain the end. Dazzled by its shallow glare, we fail to penetrate beyond its surface to the discernment of the deep-laid vital principles which underlie, and to which technique should merely give expression. Technique is a fleeting and evanescent thing. The practices of yesterday are altered today and supplanted tomorrow, but the ideals which should lure us and the fundamental principles upon which they are based belong to the eternal verities. They are the same yesterday, today, and forever. "A wise man," said the Master Builder, "built his house upon a rock; . . . and the rain descended, and the floods came,

and the winds blew, and beat upon that house; and it fell not; for it was founded upon a rock. . . . A foolish man . . . built his house upon the sand; and the rain descended, and the floods came, and the winds blew, and beat upon that house; and it fell; and great was the fall of it."

These are the types and symbols of success and failure in every age and in every effort at construction, whether it be of character or of concrete. The difference goes far beneath the superficialities of materials and technique to the visualization of ideals, the spiritual discernment and utilization of those factors which make for durability and permanence, the selection of motives, the adoption of principles, the choice of foundations. This accomplished, technique will develop and mature into the finished product, as the grain comes to fruition out of soil well prepared and properly nourished.

Technique is an expression of personality, temperament, disposition, opportunity, and there are as many variations in technique as there are in personalities and temperaments and dispositions and opportunities. But beyond all these, and deeper than all are character, the ruling motive, the governing principle, and the abiding foundation of life. These are what we seek as the bases of our efforts.

It is very patent that every bridge work restoration must be a two-part institution—the substitute or superstructure, which the operator supplies, and nature's own foundation in the oral cavity, comprising the teeth with their component tissues and their investments, each with its individual functions and relations.

The status of every tooth with which we have to deal and its investment as integral parts of the human organism compels our consideration and our treatment as a surgical undertaking; their function as parts of a mechanical apparatus requires our management as an engineering problem, and their potential esthetic value by reason of their prominence amid the features demands our care and attention from the artistic point of view. Add to these the

requirement of good workmanship which must characterize every successful undertaking, and we have surgery, engineering, art, and workmanship as the four-square, rock-ribbed foundation upon which every successful effort at restoration must be based. We may vary methods and technique, but we cannot alter these principles. Every effort at restoration which ignores or violates any of these fundamental essentials is a failure to the extent of such neglect or violation, whatever apparent success may attend it, because it is inherently vicious or deficient, and because what is inherently and fundamentally wrong cannot be made right by any external show of excellence or superiority; and no amount of theorizing can make it right.

When the profession has accepted these fundamental truths and so established this immovable foundation as the basis of our efforts, then we can begin to discuss intelligently types and systems of restoration, and the details of technique by which they are accomplished.

But it is idle to talk about removable bridge work or fixed bridge work, about the shell crown, the Alexander hood attachment, the Hinman "2-step, 3-pin," the Carnichael attachment, the telescoping crown, the split bar, or any other method or device or detail until we have gone beyond these secondary things, and laid our foundation on the solid rock of the primary requirements. Then and not until then shall we have some standard of perfection, as it were, as a basis for testing and comparing the merits of our systems and our technique; and with this accomplished we shall be less fascinated by gimcracks and fripperies, and ask ourselves the serious question, "Is this the best surgery, is this the best engineering, is this the best art to apply in this particular case?"

Much has been said in recent years about the lack of standards in bridge work and the necessity for standardization of bridge work. These things are true and important, but we cannot standardize personalities and dispositions: we have to begin at character. Just so, we cannot standardize systems and

methods and technique until we have gone to the root of the matter, and standardized or comprehended the fundamental principles on which they are based and out of which they grow. When these fundamentals are established in our thinking and our practice the details of system and method and technique will take care of themselves. All of our efforts in restoration must come under one of these four heads. For example, many essayists and discussers have harped on the necessity for anatomical conformation, which is well as far as it goes, but is not basic. It is merely a means to an end. If we analyze anatomical conformation we find it serves three distinct purposes, protective, mechanical, and esthetic. Its achievement, therefore, so far as it relates to the protective function comes under the head of surgery; so far as it concerns the mechanical it pertains to engineering, and so far as it has to do with the esthetic it belongs in the realm of art. So it is with the preparation of the abutments, the management of the occlusion, and all the other details with which we concern ourselves. In the last analysis they all are traceable to one of these four fountain-heads of successful restoration—surgery, engineering, art, and workmanship.

All of our restorative effort that relates to the pathological-physiological status and relations and welfare of the teeth and tissues of the oral cavity is within the province of surgery. Everything that pertains to the mechanical-physical relations, requirements, and functions is in the domain of engineering. Whatever has to do with esthetic values and cosmetic improvement and integrity belongs to art, and all of our constructive operative and prosthetic effort is comprised in workmanship.

May I quote at this point just one paragraph from a former article:

It is not enough that we be merely good jewelers, and our productions conformed even to the highest standards of that art or trade. A bridge-work restoration in its highest development is not a mechanical operation, and the man who performs it on that basis has failed to catch the vision and to comprehend its true mission. To be sure, the details of its execution are mechanical, just as no surgeon ever took a scalpel and opened into the abdominal cavity that he did not do a mechanical thing. But it is the subject of our operations and the object for which we perform them that lift them out of the sphere of butchery and mechanics into the realm of surgery and art. To serve its highest mission every bridge-work operation should combine good surgery, good engineering, good artistry, and good workmanship, and any operation which falls short in any of these particulars fails in the degree in which it is thus deficient.

It has not been the purpose of this paper to elaborate the details of the practice of surgery, engineering, art, and workmanship as they apply to oral restoration, but to try with all the emphasis at my command to establish in our thinking the necessity for anchoring our efforts, not in the shifting sands of technique nor the insecurities of systems and methods whose chief claim to consideration is the mechanical excellence of their products, but to the only secure and abiding foundation—laid four-square in surgery, engineering, art, and workmanship—which alone can impart to system and method and technique that excellence of character, durability, and permanence that withstand the ravages of time and the combative forces which operate against them, symbolized by the house founded upon a rock.

149 BROADWAY.

The Diagnosis of Malocclusion in Its Early Stages.

By FRANK A. DELABARRE, A.B., D.D.S., M.D., Boston, Mass.

(Read before the Connecticut State Dental Society, New Haven, Conn., April 18, 1918.)

THE necessity for early recognition and diagnosis of malocclusion is the logical outcome of the advance that has been made in the science of orthodontia in the last few years. In the treatment of malocclusion it is now well established that "preventive orthodontia," undertaken very early in life, just as soon as a positive diagnosis can be made, has supplanted the old "corrective" idea of waiting until the twelfth year or later. The results obtained are much nearer the "normal" in every respect, and the expenditure of time and effort is very considerably less. Another decided advantage is the almost complete elimination of pain. Nature responds to the mechanical stimulus of the appliances more readily and successfully at the time when growth in the different zones and directions is due to occur.

The conception of normal occlusion as presented in the various textbooks is that of the adult, and there is no consideration given to the normal below the age of twelve. There is and must be a normal for every stage in facial development, and while the deciduous and mixed dentitions resemble the adult occlusion in the arch-curve arrangement, there are several physical characteristics that differ materially from those of the adult occlusion, particularly the overbite of the incisors and the absence of the curve of Spee.

Through this new conception of the normal course of development from infancy to adult life the malocclusions occurring at twelve years of age and later are seen to be only progressive and very complicated stages of maldevelopment,

which can be traced step by step back to very small and simple deviations from the normal, occurring at a very early age.

The present state of our knowledge shows that malocclusion starts very early, and that it can be diagnosed surely between three and five years of age. Study of neglected cases of malocclusion develops the fact that, once started unmissably toward maldevelopment, they never tend to correct themselves, but always grow progressively worse.

As to the prevalence of this unfortunate condition, it may be stated that 95 per cent. of the children under sixteen examined at the Forsyth Infirmary presented cases of malocclusion.

There is no scientific data at hand to support it, but a conservative estimate of the whole situation would give 80 per cent. of children in America at the age of three years enjoying normal occlusion, while 80 per cent. of adults have malocclusion.

ETIOLOGY OF MALOCCLUSION.

In considering the etiologic aspects it may be briefly stated that malocclusion is seldom a local disturbance due to local causes with purely local effects, but is more often merely a local "symptom" of larger and more remote causes that are producing similar results elsewhere in the bodily economy, such as organic defects or functional derangement attended by the consequent end results that are serious in their menace to health.

Two deductions may be drawn from this phase of the subject. Many of the causative factors are operative long be-

fore a positive diagnosis can be made, and cannot be eliminated or corrected by mechanical means alone.

Malocclusion deserves more attention from the profession because of its undoubted effect on the general tone and health of the individual. The diagnosis of any case rests on the conception of the normal, and a recognition of deviations therefrom.

EARLY DIAGNOSTIC SIGNS OF MALOCCLUSION.

It is not the purpose of this paper to describe in detail normal occlusion and its development, but to present a series of the most frequent symptomatic and diagnostic signs, occurring early in life, that may be relied upon unquestionably

FIG. 1.

as indicating an already existing malocclusion that has passed the stage when its diagnosis might be a matter of opinion or dispute. They are presented as personal convictions based on years of experience in private practice and in handling large public clinics. Do not underestimate the importance of these signs because of the small degree of deviation from normal relationships, as their significance lies in the interpretation of the causes that are responsible for these small, first digressions from the normal direction of growth and the inevitable progressive malocclusion that will result.

In Fig. 1 we have illustrated an upper arch with the teeth in a good arch curve, with proper contacts between the teeth. Actual measurements of these teeth, as

measured by the Bogue system across the palate at the gingival line of the second deciduous molars, show 28 mm. Dr. Bogue says that any child of four, who measures 28 mm. or less, has delayed development, and has not the physical vigor to get back to normal, and will inevitably have progressively irregular teeth.

FIG. 2.

Even with a good arch curve and good occlusion, it is already a case of malocclusion, because the child at three years had this identical arrangement of the teeth. Between three and five years of age there has been no growth; so what is normal at three years of age, becomes abnormal at five.

FIG. 3.

This measurement of Bogue of 28 mm. means this: In all the cases with which he has come in contact, there has not been one case which has presented this measurement or less but what has developed a malocclusion later.

We may take this as the starting-point to get an estimate of our cases.

Fig 4 is the front view of a case of malocclusion. This represents the normal arrangement of the teeth of a child

of three years of age with a small amount of overbite and with a registration at the median lines; but if the child arrives at the age of five years without the evidence of growth and development, at that age it constitutes a malocclusion.

The evidence of growth seen at the age of five is the appearance of the inter-spaces coming between the incisors. As the permanent teeth grow and erupt, the

FIG. 4.

force of the growth and eruption causes the spreading of the incisor teeth, as is shown in Fig. 3, which is the normal for that age.

I want to call your attention to two or three points with regard to the normal deciduous denture. There must be the registration of the median lines, and the arch curve must be even and regular. Fig. 8 shows that the curve of occlusion

FIG. 5.

so called—the curve of Spee—the curve of compensation, is absent at this age, and we have an almost exact plane of occlusion. This is one of the distinctive differences in the child's dentition.

One other point in regard to the antero-posterior relation: In the adult, the point of the upper cuspid comes between the lower cuspid and first bicuspid teeth. In the deciduous dentition, the forward position of the lower cuspid is very much less than in the permanent dentition.

The distal edges of the upper and lower deciduous second molars are almost—if not exactly—in the same vertical plane. This is the diagnostic sign of the normal antero-posterior position of the mandible in the temporary and mixed dentition.

In Fig. 2, there is a disturbance of the lower arch curve. Here we have rotation of the left central and lateral teeth. These teeth are out of their proper position in the arch curve, and when this occurs, together with a narrowing of the arch itself, it is a positive diagnostic sign of an existing malocclusion.

Fig. 5 shows the spaces between the lower incisors beginning to appear, and we have a good arch curve. It may measure even more than the 28 mm. across the arch. It may answer all the requirements of normal occlusion, except one, and still be a malocclusion, and that requirement is that the incisor median lines shall coincide. The lower mesial line is shifted to the left. This is extremely important, because of the significance that attaches to it. It means that there is beginning, and has already progressed to a considerable degree, a lack of lateral symmetrical growth, and it may or may not result in a cross-bite on one side or the other.

This class of malocclusion is one of the most difficult the orthodontist has to deal with, presenting very difficult problems. The proper time to correct this is when it first starts wrong, because in all of the cases that show a deviation, if the arches are restored to harmonious and normal widths, the deviation will correct itself automatically; but where it progresses to twelve or fourteen years of age, we have a deviation in the development of the entire face—the mandible is thrown to one side, the nose is divergent from the median line of the face, and there is a twisted facial expression; and it all starts in this lack of symmetrical lateral development.

Another class of case is shown in Fig. 6, where there is an excessive overbite of the upper incisor teeth. They are hiding the lower incisors. The significance of this condition lies in the fact that it is not always, and in fact is sel-

dom due to the elongation of the upper incisors, but is more often indicative of a lack of vertical development in the deciduous molar region.

FIG. 6.

When you see a case with the excessive overbite, that child is not growing vertically as fast as it should in that region, and it is a positive indication of an ex-

FIG. 7.

isting malocclusion, and should be dealt with immediately.

Fig. 7 shows infra-occlusion of the deciduous incisors. This is generally caused by a faulty tongue habit.

FIG. 8.

Fig. 9 represents a disturbance of the antero-posterior position of the mandible, it being too far back in relation to the upper. According to Angle's classifica-

tion, this is a class II case, or distal occlusion.

Fig. 10 shows the reverse of this; where the lower jaw is thrust too far forward or, according to Angle, a class III case.

These are the seven diagnostic signs of malocclusion most frequently met in

FIG. 9.

studying these cases of development. They may occur in various combinations, but the existence of any one is sufficient ground on which to begin correction.

These may be used by the general practitioner to help him to give proper advice to parents who consult him in regard to their children's occlusion, and

FIG. 10.

it is hoped that the profession will cease advising parents to "Wait until the child is twelve or fourteen," or "Let us wait and see if it will not tend to correct itself."

520 BEACON ST.

[See also *Discussion*, as reported under "Proceedings of Societies," this issue.]

History of the Dental Society of the State of New York.

By WM. CARR, D.D.S., New York, N. Y.

(Read at the fiftieth anniversary meeting, Saratoga Springs, June 13, 1918.)

TO give in detail the history of this society, which has reached a maturity of fifty years, would both sorely tax your patience and far transcend the time allotted for this paper. It must suffice, therefore, to sketch as briefly as may be what the society has done toward effecting the purpose of its organization.

THE STATUS OF DENTISTRY PRIOR TO 1868.

Prior to the year 1868, there was no law in this state regulating the practice of dentistry. Popular opinion failed to realize the scope and importance of dentistry or to hold it in due esteem. Even the courts in various jurisdictions failed to do so, or to rate it as a profession; and even today it is not universally so rated. Dentistry has been held in adjudicated cases to be a handicraft and its operative instruments to be 'mechanics' tools, exempt as such from attachment and levy of execution. It has been held to be a mercantile employment, and contracts of its practitioners to be within the statute of frauds requiring them to be in writing under certain circumstances. In France it has been said to be an art, and dentists as modelers have been classed as artists in a humble way. Curiously enough, Griswold, whose case was carried to the Court of Appeals, classed himself as a "facial artist." It has been graded with truss-making and midwifery. Even persons otherwise intelligent have believed, as many still believe, that any person able to extract or fill a tooth or make a set of artificial teeth is a fully equipped dentist.

The practice was formerly in the hands of blacksmiths and barbers, and we yet find among our immigrants that barbers are resorted to for extraction of teeth or alleviation of toothache.

That dentistry remained so long in this low estate was largely due to its practitioners. Not only has vulgar advertising by the exhibition of showcases and like means tended to hinder the recognition of our profession as a specialty of medicine in the large sense, as is rhinology, laryngology, otology, or ophthalmology, each of which treats an organ lying near the oral cavity and affected by its conditions, but leading members of our profession have stoutly contended that dentistry is absolutely distinct and apart from medicine. This is not the time to discuss that opinion. But so much is there in a name that, were dentistry known as stomatology, laymen, at least, would class it with the other medical "ologies." Some courts have distinctly classed dentists as medical men. And it is obvious that in so far as they adopt systemic and operative treatment, they are acting as physicians or surgeons. The borderline cannot be marked other than by the statutory definition.

Physicians have been held by the courts in some jurisdictions to be authorized to extract teeth as part of their professional work; to what extent dentists may operate they have not distinctly defined. But in a North Carolina case some years ago the question of whether or not a dentist was a physician was decided upon facts not creditable to the member of our profession concerned. Under the law of that state whisky could be sold by drug-

gists only upon a physician's prescription. A dentist prescribed a quart for a friend as a remedy for toothache, signing his prescription Dr. So-and-so. The druggist making the sale defended the suit on the ground that it was made on a doctor's prescription, but the court held that a dentist was not a physician, and added that this was fortunate, inasmuch as if dentists could prescribe a quart of whisky for one aching tooth, North Carolina would soon be in a bad way considering that there are thirty-two teeth in the human mouth. It was a poor exhibition of judicial humor, but the facts were serious, doing appreciable harm to the offender's profession.

There were able practitioners, skillful with their hands and scientific in their treatment before any law regulating the practice of dentistry was enacted. Natural talents and aptitudes will always assert themselves, but the proposition that the average man needs methodical training and education to fit him for his work scarcely seems to admit of argument. Yet it has not always been easy to assert this simple truth against ignorance and prejudice.

ORGANIZATION OF THE STATE SOCIETY.

When this society was organized the study of dentistry was carried on for the most part under private preceptorship, and the standard of instruction necessarily varied according to the competence and conscience of the individual instructors. The New York College of Dentistry, incorporated by Chap. 264 of the laws of 1865, was then the leading dental college of the state, if not of the country. It conferred its degree after a four months' course. In 1852 the New York College of Dental Surgery had been incorporated, but it graduated only one student, our colleague Dr. E. A. Bogue, and became moribund. An effort to revive it, even with such men as Abram S. Hewitt and General George B. McClellan upon its board of trustees, failed. Today, under its revived charter, it flourishes as the College of Dental and Oral Surgery of New York, requiring a four years'

course of nine months in each calendar year.

Medical practice was also in 1868 substantially free to all. Injudicious enforcement of the medical laws that had been put upon the statute-book in the eighteenth century and amended by degrees had led to their repeal—in fact if not in name—by the law of 1842, making unlicensed practice a misdemeanor only in cases of injury from malpractice. The college courses were short, not only in this state but elsewhere; nominally two years, often completed in less time. The degree of M.D. was conferred with what today would be deemed recklessness in a dental college. It is to the credit of the Woman's College of the New York Infirmary that it was the first to exact a three-year course of study, and when Harvard, about the year 1870, made the same requirement, the number of its students fell from a large number to about half a dozen, only to increase rapidly when students seeking medical education rather than a mere medical degree flocked to the school where that education was given.

THE FIRST DENTAL LAW OF THE STATE.

It was from appreciation of these conditions and the incident evils, both to the people at large and to the profession, that this organization came into being under Chap. 152 of the laws of 1868, entitled "An Act to Incorporate Dental Societies for the purpose of Improving and Regulating the Practice of Dentistry in this State." Those were the purposes of our incorporation—to improve the practice and to regulate it. Certainly those purposes have been accomplished; slowly, painfully, step by step, against opposition from many quarters inside as well as outside of our ranks, and not without criticism, some of it made in good faith, more out of ignorance, much out of malice.

But the result has crowned the work. The standard of education has been advanced. The meager course of four months' perfunctory study of regional anatomy, materia medica and therapeu-

tics, chemistry, physiology, covering digestion and circulation, and prosthetic dentistry, has been enlarged to a course covering four years. Preliminary education of students, at least to the extent of a high-school course, has become a requirement of admission to the colleges, which are equipped for their work to a degree undreamed of in time past. Clinical instruction and laboratories for chemical, physiological, histological, bacteriological and prosthetic work are provided. Under the statute, illegal practice, the sale of diplomas, false personation, and other frauds are punished.

By abolishing the diploma standard of license and requiring graduates of colleges to pass examinations before a state board a certain uniformity of license has been attained, and the diplomas formerly issued as articles of commerce by the so-called "diploma mills" have ceased to have value in this state. That all the evils against which our faces were set have been abolished it would be foolish to contend; but they have been lessened. If the law has failed to punish every offender—and all laws must so fail—it has been nevertheless a schoolmaster bringing both laymen and practitioners to a higher appreciation of ideal conditions. Law alone cannot, unless sustained by public opinion, regulate conduct.

The illegal practice of a profession is what is called *malum prohibitum*—it is wrong, that is to say, only because it is forbidden. Crimes that are *mala per se*, that is to say, against the common sentiment of mankind—murder, theft, and other acts originating in evil intent—are and always have been committed in greater or less degree despite laws directed against them. How, then, can one expect to prevent entirely the commission of acts which do not necessarily involve evil intent, but which in the absence of statutory prohibition are perfectly lawful and even commendable.

When Dr. Lorenz of Vienna came to this country to demonstrate his bloodless operation on the hip joint, he was technically violating the law, inasmuch as he was not licensed. He was nevertheless

invited to make the demonstration at Bellevue and Cornell. There were those, however, who felt incensed because he was not arrested, and in Chicago he was actually required to take out a license, perfunctorily granted, before being allowed to give a demonstration—a perfect example of the fact that it is the spirit that keeps the law alive and the letter that kills it. It is this narrow spirit, the spirit of small jealousy, in most instances animated by desire for personal gain or professional aggrandizement, that caused the medical laws in England and in this country to fall into disuse.

Both medical and dental legislation are enacted under the police power of the state, primarily for the protection of the people and the common welfare against harm resulting from ignorance and unskillfulness on the part of those from whom the common law requires knowledge and skill. Secondarily, such legislation may operate for the advantage of the licensed calling, but that is not the ground upon which courts sustain it, and in the enforcement of legislation by the Law Committee of this society, that truth has been kept in view. The spirit of the law has been recognized, and out of that recognition has grown most of the criticisms directed against those charged with the statute's enforcement. It is also because of that recognition that we have been able by degrees to enlarge the scope of the law.

THE EFFECT OF THE DENTAL LAWS UPON DENTAL EDUCATION.

It has been said already that your patience would be exhausted by a detailed recital of the work achieved by the society. Since its organization, twenty-two acts of the Legislature bearing upon dental practice have been passed, some of them being consolidations of work already accomplished. A number of proposed enactments intended to benefit individuals and lower the standard established have been defeated by constant vigilance. The constitutionality of the law as formulated by the society has been sustained in the case of Griswold already referred

to, which was obstinately contested in all our courts until his conviction in the New York Special Sessions was finally affirmed by the Court of Appeals.

The law of 1868 authorized dentists in the eight judicial districts of the state to convene on the first Monday of June in that year, in number not less than fifteen, at specified places, to elect officers, and when organized to choose eight delegates to meet in Albany on the last Tuesday of that month, and, if the delegates were not less than thirty-three in number, to organize the Dental Society of the State of New York. It provided for the appointment of censors by each district society, whose duty should be carefully to inquire into the qualifications of all persons who should present themselves within the districts where they resided for examination, and report their opinion in writing to the president of said district society, who in turn was required to issue to persons recommended by the censors a certificate of qualification, countersigned by the secretary, and under the society's seal. It also authorized the State Society to constitute a state board of eight censors, one from each district, to examine all persons entitled to examination under the act and presenting themselves therefor. Upon the recommendation of this board, it was the president's duty to issue a diploma under the society's seal and countersigned by the secretary.

All dentists in regular practice at the passage of the act, all having diplomas from a dental college of the state, and all students who had studied and *practiced dental surgery* with accredited dentists for a term of four years, were entitled to present themselves for this examination, and a deduction from this term, in the case of students who after the age of sixteen had pursued any of the studies usual in the colleges of the United States, was made for the time they had pursued such studies, not exceeding one year. A deduction of one year was also made in the case of a student who had attended a complete course of lectures in any incorporated dental or medical college in the United States.

By Chap. 331 of the laws of 1870, this diploma of the society was made to confer the degree of Master of Dental Surgery. It was made unlawful for any other society, college, or corporation to grant the said degree, and anyone falsely pretending to hold the certificate, license, diploma, or degree from the state or district society, or to be a graduate of an incorporated dental college, with intent to deceive the public, was made guilty of a misdemeanor.

In 1901 it was provided by Chap. 215 of the laws of that year that no dental degree should be conferred in this state except Doctor of Dental Surgery, the Board of Regents being authorized to confer this latter degree upon those already holding this society's degree of Master. There was opposition to this change of the law, very warmly urged by some whose opinion was entitled to weight, but the majority in favor of it was large.

No law is of great value that does not have a sanction, that is to say, does not provide adequate punishment for its violation. This the law of 1868 failed to do. It did, however, contain the provision that this society should be entitled to all the privileges and immunities granted to the Medical Society of the state, which, literally construed, would have entitled us to grant medical diplomas. No one was obliged to submit himself to examination, no license to practice was required, and consequently no penalty for unlicensed practice could be imposed. The great result of the statute was the creation of state and district societies, whose persistent efforts for the betterment of the law have educated slowly both the profession and the public to a realization of what the qualifications of a dentist should be. The barriers to advancement have been gradually overcome. With the law's amendment, and, as we believe, in part at least on account of it, the standard of education has been advanced, and that advance has been reflected in the papers read before the society, which, dealing at first with strictly technical and practical matters of technique, or with general exhortations di-

rected to the improvement of the profession, have been increasingly scientific in their nature.

In 1877 and 1878 strenuous efforts were made to obtain a law requiring the diploma of a college or of the State Society as a prerequisite to license. But the proposed measure met strong opposition, especially from Brooklyn, and was defeated. Its opponents urged that the measure would deprive practitioners of their livelihood, that the diploma was a fetish, importing no special skill and knowledge, and that the school of experience was the best educator. In the following year, however, this step in advance was made by Chap. 540 of the laws of 1879, a short act declaring it a misdemeanor for anyone to practice dentistry for fee or reward without a diploma from the society or an incorporated college recognized by the society, violations of the law to be punished by a fine of not less than \$50 or more than \$200. It was provided, however, that nothing in the act should apply to persons engaged in practice at the time of its passage. This also met the objection that the law would deprive men of their livelihood. The other step in advance made by this law was a requirement that within sixty days from its passage every practitioner should register in the office of the clerk of his county. Thus, after the lapse of eleven years from its organization, the society obtained the requirements of license and registration such as they were. Many, however, failed to register, and two years afterward, in 1881, an act was passed extending the time of registration. The enforcement of the law was at first intrusted to special committees appointed annually, and without resources.

In 1875 Dr. C. A. Marvin, from the committee appointed to prosecute violations of the state law, made a verbal report that no action had been taken, and a resolution was adopted to refer that report to the same committee, and to give them a year's longer time for prosecution. In the following year that committee—Drs. Marvin, Austin, and Harvey—reported that only one case of

violation of the law had been brought to their notice; that as the person alluded to had died, no action had been found necessary, and that it was hoped that no need of any further appointment could be found to exist. In the following year another special committee upon the amendment of the dental law, composed of Drs. Francis, Hill, and Daboll, reported a short act prohibiting practice by any person not having received a diploma from some incorporated college or the State Society. The report was adopted and nothing more done.

APPOINTMENT OF A PERMANENT COMMITTEE ON DENTAL LAW.

A special committee was again appointed, with like meager results, and in 1883 a permanent committee on dental law was created, which in the following year reported that although it had been notified of its appointment, it had received no definite instructions as to procedure, whether to await charges from a district society or to proceed upon its own initiative. It did report, however, action upon various cases, in none of which were legal proceedings instituted. In the following year, 1885, this committee reported their efforts in a number of cases, and concluded by suggesting that the committee be allowed to employ counsel, and this they did in the year 1888.

From that time on, prosecutions were steadily conducted, with the result that in some years conviction was obtained in every case tried, and out of the hundreds of prosecutions convictions have been obtained, so far as I have been able to estimate, in over 90 per cent. A few civil cases also arose. The first was a mandamus proceeding by one White to compel the writer as a member of the State Board of Censors to issue a certificate allowing the relator to register as having been engaged in practice prior to 1879. In that year he had attained the mature age of fourteen years, and the application was denied. Actions also for false arrest or malicious prosecution were brought and defeated. Constant efforts were made to extend and enlarge the so-

called student clause allowing persons under the instruction of preceptors prior to the licensing act to be admitted to examination without other qualification. All these attempts were defeated, and the clause finally eliminated.

It was found that while prosecutions in the county of New York—which after the first few years were tried in the Court of Special Sessions, composed of three justices—were almost invariably successful, it was extremely difficult to procure convictions in other parts of the state. Two typical cases illustrated this difficulty. Complaint was made of one B., of H. county. He was unregistered and unlicensed. He had left Massachusetts under a cloud. He falsely qualified as an expert in an assault case, testifying that he could tell from the appearance of the alveolar process whether a tooth had been pushed in or pulled out. The action in which he so testified was founded on a woman's complaint that her brother-in-law had knocked her tooth down her throat, and the brother-in-law's defence was that in trying to protect himself from her assault his finger got into her mouth, and in pulling it out he had extracted the tooth.

The case against B. was sent three times to the grand jury. Its members being friendly to the accused sent for him, and discussed the constitutionality of the law. Mr. Justice Kennedy of the Supreme Court on the third occasion instructed the grand jury that their duty was to pass upon the facts, and that they had nothing to do with the constitutionality of the law. Finally B. died. The whole matter turned largely upon the unpopularity of the complainant, who had been an expert in the assault case in opposition to B. Feeling ran so high that a local newspaper said editorially that while of course B. was technically guilty, no grand jury in the vicinity would indict him.

Another case in Warsaw showed the influence of local feeling. Two licensed dentists went there to practice. They complained that a practitioner, a native of the place, was unlicensed. The grand

jury sent for the book of registry, and finding that neither the complainants nor the accused were registered promptly indicted the complainants, but refused to indict the equally guilty accused. These examples are only some of many.

The society's prosecutions of corporations were also successful. It may be considered the settled law of this state that corporations cannot practice law, medicine, or dentistry, or it might have been so considered prior to the passage of the dental act now in force, which, contrary to these decisions by the courts, allows corporations practicing dentistry prior to its enactment to continue in practice, although the practice of law and medicine, implying personal relation between the practitioner and his client or patient, is confined to individuals.

Throughout the time during which the society has endeavored to enforce the law, it has labored under the disadvantage of insufficient funds. Under the original acts of Legislature the fines were given to the public-school fund. As there were no prosecutions, that fund did not benefit. By amendment, only the excess of receipts from fines over cost of prosecution was to be so disposed of, and as there was no such excess, again the school fund reaped no harvest. Eventually all fines were given to the society, but never did they cover the cost of prosecution. So also the excess of fees for examination over cost was given to the society. The cost of prosecution in no year has been equal to the salary of a deputy district attorney in New York, while societies for the Prevention of Cruelty to Children and of Animals, aided by individual subscriptions and large endowment funds have had incomes amounting to as much as \$100,000 a year.

Under the law of 1916, prosecutions are now required to be initiated by complaints to the Regents under oath or sustained by other satisfactory evidence. If upon investigation they are found to be true the Regents refer the complaints to the Attorney-general for prosecution, the fines being given to the State Board of Dental Examiners. Annual registration

is now required. The advocates of this change of the law argued that out of the receipts from this source a large fund would be annually available for prosecutions. What the results will be remains to be seen; it is hoped that they will be commensurate with the increased resources.

Apropos of the criticisms made of the society's prosecutions, it should be mentioned that they emanated largely from members of the Eastern Dental Society of New York and of the Allied Dental Council, and were spread by their organ. The Dental Council employed as its agent one M., who had been employed for a few weeks by the Second District Society, and subsequently by the Law Committee of the State Society, upon representations that he knew of some 360 unlicensed dentists. He failed to give their names; his methods were unsatisfactory, and he was discharged. Thereafter he was employed by one R., twice convicted on the society's complaint, and as he admitted on the witness stand, was desirous of "getting even."

M. circulated defamatory stories attributing "grafting," as it is called, not only to former agents, but to the chairman of your committee and its counsel, representing them to have collected enormous sums from unlicensed practitioners. He included in his stories the offices of district attorneys of New York and Kings counties, which he said were controlled by your counsel, a judge on the bench, and others. Charges were preferred against him to the Comptroller of the state. Every opportunity was given him to substantiate his statements, and his license as a detective was revoked. The deputy state comptroller, who heard the charges, in a written opinion found them to be groundless. He, M., sued out a writ of certiorari to review this finding, and the appellate division of the Third department, after hearing arguments upon a voluminous record of over a thousand pages, unanimously ordered dismissal of the writ with costs against M., and thereafter denied his application or appeal to the Court of Appeals.

In the course of that hearing it transpired on the cross-examination of Dr. R., a witness for M., that he had given a certificate to the Regents of good character for one M. G., also a witness for M. This man had previously testified in defense of one DeL., who had been twice convicted by the State Society, and again prosecuted by the Allied Council. G. having testified that he had done the work that DeL. was charged with doing, after an interview with Dr. R. made affidavits that his testimony was false; in one way or the other he had sworn falsely. Dr. R. admitted that he communicated with G. in the course of the last prosecution, and had known him only a few months. Nevertheless he subsequently certified to the Regents that he had known him three years, and believed him to be of good character and worthy of admission to the dental profession. Charges were preferred against him before the state board, and after a hearing he was suspended from practice for a year. The Regents confirmed this finding. He also sued out a writ of certiorari and the appellate division dismissed his writ with costs.

These prosecutions necessarily affected the Law Committee of the society, and reflected upon the society itself. They consumed months of time and involved much labor on the part of counsel who conducted the prosecution, but no compensation has been received by him, and his disbursements incident to attending the sittings of the court in Saratoga and Albany have not been repaid.

The law as it exists is not perfect. It is the result, as so many laws must be, of compromises, such as permitting corporations to practice dentistry, despite the rulings of the courts. But it is hoped that before the centennial of the society arrives, the educational advance in the profession will be as great commensurately as it has been in the past—that the law will be perfected and made a simpler statute, and that dentists will have achieved their true position as prac-

tioners in a special field of medicine and surgery. Until that condition has been brought about, the question will always arise whether operations properly

within his scope constitute practice of medicine and violations of the medical law.

560 FIFTH AVE.

The Conversion of India Rubber into Vulcanite.

By GEO. B. SNOW, D.D.S., Long Beach, Cal.

THE fact is well known that caoutchouc or India rubber, when mixed with a certain quantity of sulfur and exposed to heat, turns into a hard, hornlike substance, totally unlike the compound from which it was formed, which is known as vulcanite. The use of this substance in dentistry is universal, by far the greater proportion of artificial dentures being composed of vulcanite as a base. Although the material is easily worked and the results obtained with it are fairly satisfactory, the artificial dentures produced usually contain defects which are sometimes imperceptible, but which nevertheless exist. These come from a lack of knowledge of the phenomena attendant upon the hardening of the rubber compound by its exposure to heat, the substance being so easily worked that any inquiry into the phenomena attendant upon vulcanization is usually thought to be unnecessary.

About forty years ago the attention of the writer was directed to this subject by some remarkable statements given out by Dr. Seabury in his promotion of a rather peculiar form of vulcanizer which he was then introducing, and which is now almost forgotten. Some of these statements ran counter to the writer's experience, and induced him to experiment for the purpose of ascertaining their truth or inaccuracy.

One of these strange assertions was to the effect that the sudden application of steam pressure to the rubber compound would prevent the occurrence of spongy

rubber, the pressure advocated being as high as 120 pounds to the inch, which pressure corresponds to a temperature of 350° F. Experiments showed this statement to be fallacious. In conducting them, pieces of considerable thickness, with flat sides, were vulcanized, and it was found that when a temperature was employed which produced a mass that was solid to the center, the sides of the piece were invariably concave. And upon taking the specific gravity of one of these pieces and comparing it with that of the unvulcanized gum, there was found to be a decided increase in this respect in the vulcanized piece. It was thought best to go farther with these experiments, and a metal mold was designed consisting of a flat plate of brass which would produce a flat circular mass a quarter of an inch in thickness and a little more than one and three-quarter inches in diameter, a smaller cavity being provided and connected with the mold by a narrow passage, to receive the rubber which would be expelled from the mold as its contents expanded by heat. This smaller cavity is called the overflow chamber, and the rubber which escapes into it is known as the overflow. A flat plate on each side of this central piece completed the mold, the parts being clamped firmly together with bolts.

EXPERIMENTS IN VULCANIZING RUBBER.

In performing the experiments the mold was packed full of rubber com-

pound, closed by bolting its parts together, and then boiled. The expansion of the rubber when heated expelled a small quantity of it into the overflow chamber. This overflow was removed, the amount of rubber remaining in the mold being then sufficient to completely fill it at the temperature of boiling water. This mass of rubber was then removed from the mold, weighed, and its specific gravity taken, again inclosed in the mold, and vulcanized. It was then again weighed, including what had escaped into the overflow chamber during vulcanization, and its specific gravity again taken. The overflow was then weighed separately.

It was found that the sides of the flat circular piece thus produced were invariably more or less concave, and the specific gravity of the mass was considerably increased by vulcanization. It was also found that the diminution in bulk of the mass as shown by the concavity was nearly equal to the bulk of the overflow, so that the mass which was contained in the large chamber of the mold was diminished in its bulk, first, by its shrinkage in vulcanizing, and again by the expulsion of a part of the contents of the mold into the overflow chamber. Taken together, the diminution in bulk of the piece of vulcanite remaining in the mold was found to equal from 4 to about 9 per cent., depending upon the amount of foreign matter incorporated in the rubber compound.

The results of some of these experiments have been tabulated for inspection. (See Table on following page.) A wide difference is seen in the figures for pink rubber, which has in its composition an excessive amount of coloring matter, as compared with the base-plate rubber. It shows less expansion by heat, and less shrinkage, the base-plate rubbers varying in these respects according to their color, the darker ones showing more expansion and shrinkage and the lighter ones less. The diminution in bulk varied from a little over 2 per cent. for pink rubber to over 9 per cent. for a sample of black rubber compound.

The diminution in bulk consequent

upon vulcanizing rubber is the result of two causes: (1) Its shrinkage, which is a permanent molecular change involving an increase in specific gravity, and (2) its contraction by cooling, a property which is possessed by vulcanite to a very marked degree, as it expands by heat and contracts by cold much more than any other solid substance. The distinction between the two words, shrinkage and contraction, should be kept in mind, as shrinkage refers to a permanent molecular change, while the change denoted by the word contraction is of a temporary nature, being the opposite of expansion, either being produced at will by a change in the temperature of the mass.

These facts account for the troubles encountered by dentists in their vulcanite work. If the vulcanizing is done, as it usually is, in a flask which is completely closed before it is placed in the vulcanizer, its parts being rigidly held together by bolts, it is necessary to cut escape gates for the reception of the overflow rubber as it escapes from the mold when it is heated, and it is apparent from what has been said that when the vulcanizing process is completed there will be a deficiency of vulcanite in the denture, the result not only of the shrinkage of the gum in vulcanizing, but also of the expulsion of a part of the rubber compound into the escape gates as it is heated to the vulcanizing point. There must, then, be a surplus of rubber compound, *i.e.* more than the mold will hold when closed, at the beginning of the process, and the closure of the mold must be effected gradually as vulcanization proceeds, and as the mass grows smaller by its shrinkage.

By vulcanizing samples at the same temperature and at different times, increasing the time gradually from ten minutes at the start by short intervals to the full time for vulcanization, and afterward taking the specific gravity of the samples, it was found that shrinkage takes place more rapidly during the first half of the vulcanizing process than thereafter. It follows, then, that if the flask is completely closed when it is placed in the vulcanizer, the vulcanizing

process will not have progressed very far before sufficient shrinkage of the rubber will have taken place so that it will no longer completely fill the mold. It will adhere to the plaster surfaces and will in consequence leave the smoother and more dense surfaces of the teeth and tooth-

the teeth, which allow the intrusion of mucus and particles of food which decay and render the denture unsanitary. This condition was more noticeable in former days, when gum section teeth were employed, but it is still present in most of the artificial dentures.

EXPLANATION OF THE TABLE.

All weights in the Table are in grams. All bulks in cubic centimeters.

All samples were vulcanized at 75 lb. by the steam gage, it being the same as 300° F. by the mercury bath thermometer, or 320° actual temperature.

Columns 3 and 7 show the weight and also the bulk of water equivalent to the respective samples—as a cubic centimeter of water weighs 1 gram.

All the vulcanizing was done in the same brass mold, which was closed by bolts without springs, and had a gateway leading to an overflow chamber, which received the rubber expelled from the mold as it was heated from 212° F. to the vulcanizing point. Capacity of mold at 70° F., 10.710 cc.; at 212°, 10.759 cc.; at 320° (75 lb. pressure), 10.796 cc.

The discrepancies between columns 1 and 5 are due to the absorption of a small quantity of water by the rubber when vulcanizing; showing that vulcanite is slightly porous. The amount of water absorbed is about half a drop for a sheet of rubber. *Rubber compound does not lose weight by vulcanizing.*

Column 11 denotes the weight of rubber expelled from the mold as the sample is heated from 212° F. to the vulcanizing point. Column 12 shows the bulk of the same.

In column 13, the shrinkage shown in column 9, which is the difference between columns 3 and 7, is added to the overflow, column 12, and shows the total amount of deficiency of vulcanite in the mold when the

vulcanizing process was completed. Column 14 gives the percentage of this deficiency. It will be noted that the deficiency is greater in the dark-colored rubbers and less in the lighter-colored ones, the light rubbers containing more foreign matter in their composition.

Conclusions.

If the flask is bolted and gateways provided for the free escape of the rubber as it is heated, the deficiencies shown in columns 13 and 14 are inevitable, and the denture will always be defective.

If spring pressure is applied to close the flask, and the rubber is confined so that none of it can escape unless the parts of the flask are separated by its expansion, the deficiency will be less than that shown in columns 13 and 14, the amount depending upon the average thickness of rubber in the case.

To produce the best results, spring pressure must be used to close the flask, the mold must contain an excess of from 3 to 5 per cent. of rubber when vulcanizing commences, and the flask must, therefore, not be entirely closed at this time. Its closing must be effected gradually by spring pressure and after the vulcanizing process has progressed far enough to cause a partial shrinkage of the rubber. For vulcanizers of the ordinary type this may be accomplished by two vulcanizations.

pins, the result being that the teeth are insecurely held upon the plate, often loosening after a short time of use. At times the vulcanite will be found to have drawn away from the overhanging shoulders of the bicuspid and molars, and again there will be pockets formed by the separation of the vulcanite from

THE ADVANTAGES OF SPRING PRESSURE IN VULCANIZING.

The ordinary method of vulcanizing, that is, by using rigidly bolted flasks and passages for the escape of rubber compound as it is heated, is, then, wholly and entirely wrong. If escape passages are

not provided and the flask is rigidly bolted so that there is no vent for the rubber as it expands when heated, it will exert sufficient pressure by its expansion to cause a yielding of the plaster mold, and to injure the fit of the denture. Some form of spring pressure should always be used upon the flasks in vulcanizing artificial dentures, allowing them to open slightly and yield to the pressure of the expanding rubber as the case is heated, and the pressure should be sufficient to close the flask upon the rubber as it shrinks during vulcanization.

Many dentists are aware of the benefits arising from the use of spring pressure upon the flask when vulcanization is going on, but very few use it in a way to gain all the advantages to be derived from it. This is an easy matter if the case presents a large area, and requires only a small quantity of rubber compound in its construction. If all the plaster is removed from one of the parting surfaces of the flask, except a very narrow margin next the mold, it is evident that there will be no escape for the rubber until after its expansion has slightly separated the halves of the flask; but when this occurs the capacity of the mold is increased, and a certain quantity of surplus rubber will be retained in it, which will compensate for the shrinkage of the mass, provided the shrinkage is not too great. If the average thickness of the denture is not over a twelfth of an inch the results obtained will be very satisfactory, but with a greater average thickness the amount of rubber retained by the opening of the mold by its expansion will be insufficient. Rubber compound flows with difficulty through a very narrow passage, and very little of it will pass if the sections of the flask are separated less than a hundredth of an inch. A considerable escape will ensue, however, if the separation is twice that amount.

For dentures having a greater average thickness and requiring a greater quantity of rubber compound in their construction it becomes necessary to prevent the complete closure of the flask until after the rubber is partly vulcanized. With the ordinary vulcanizer this will re-

quire two separate vulcanizations, the first, for somewhat less than half of the requisite time, with the flask held open by props sufficiently to allow the retention of a certain amount of surplus rubber, dependent upon the case; the second with the props removed, and the spring pressure exerted to close the flask and mold the rubber as the process of shrinkage goes on. But few dentists will go to the trouble involved in this double vulcanization, although when it is expertly performed excellent results may be obtained.

An alternative is the use of a vulcanizer so constructed that the flask may be closed in its interior, and while the vulcanizing process is going on. With such a vulcanizer the dentist has the time for closing the flask and the pressure to be exerted upon it entirely within his control, and the results will accordingly be very satisfactory.

EXPANSION AND CONTRACTION OF VULCANITE.

Vulcanite when heated expands much more rapidly than other solid substances. The figures which are available in the textbooks give the rate of expansion for only a small range of temperature, not exceeding 100° F. It is impossible to measure the rate of expansion accurately for temperatures very much above the boiling-point of water, as the samples shrink perceptibly when so heated. It is believed, however, that the rate of expansion will increase to a certain extent with the temperature to which the sample is exposed, and that it will also vary according to the composition of the vulcanite. A sample composed of pure rubber and sulfur will expand more when subjected to a certain heat than will one of which extraneous substances form a part. That is to say, pink vulcanite will expand less than the ordinary colored base rubbers, and these in turn less than a sample of pure rubber and sulfur.

There is difference enough in the rates of expansion of pink and colored base-plate rubbers to be taken into account in the construction of artificial dentures. If only a thin layer of the pink vulcanite is used to cover the base-plate gum, the

latter extending over the buccal and labial faces of the plate, the influence is not marked: but when the whole labial portion of the plate is of pink vulcanite, the plate will often be found to be warped. It will be too narrow at the extreme rear and too high in the palatal vault, and when placed in the mouth it will be found to rock and to have little or no adhesion: when worn it will be very apt to chafe and irritate the buccal surface of the gum.

When vulcanite is at a temperature at or near the boiling-point of water it becomes very flexible, and when bent and cooled it retains whatever shape may be given it; and if it is stretched when heated and cooled under tension, it will remain elongated when cool. A strip of vulcanite composed of a layer each of pink and black or red rubbers, and vulcanized between flat plates of metal, will when cool show some curvature, the hollow side being toward the base rubber. If the strip is dipped into boiling water it will when cool show very much more curvature than it did before.

A vulcanite denture is molded upon its plaster cast, and as it is expected to retain the shape and contour of the cast upon which it is molded, it should be allowed to remain in the flask until it is cold before the flask is opened, the vulcanite being held to the cast while cooling. It is under a certain amount of tension, which is relieved if the plate is subjected to a temperature high enough to soften it, the amount of change depending upon the temperature employed. Dr. Stewart J. Spence of Chattanooga, Tenn., has taken advantage of this fact. By dipping some of his dentures in water heated to 130° F. or more he found that when the denture had cooled it was perceptibly smaller; and by carefully managing the temperature of the water he was able to improve the fit of the plates.

If, after vulcanizing, the flask is opened while hot, the palatal portion of an upper plate will cool more rapidly than will that portion overlying the alveolar ridge, and because of the fact that one part contracts, as it cools, before the other, there will be a tendency to warp of the plate.

SPONGY VULCANITE.

In the prosecution of these experiments, an attempt was made to compare the behavior of the rubber samples when vulcanized at different temperatures, all being vulcanized in the same mold—one lot at 320° F. actual temperature or 300° by the mercury bath thermometer, the other at 320° by the mercury bath thermometer or 340° actual temperature. The results of these experiments were unsatisfactory, and it was found that the disks vulcanized at the higher temperature were slightly spongy in the center. Of course they showed less concavity than if they had been solid, and were not available for the purpose of taking the specific gravity of the product.

As many artificial dentures, especially those for the lower jaw, have places in them a quarter of an inch thick, it follows that they should be vulcanized at a lower temperature than 320° by the mercury bath thermometer. Vulcanite turned out at this higher temperature is not so strong and tough as that vulcanized at a lower heat, and in case of repeated repairs, which are sometimes necessary, the vulcanite will be found to have lost a great part of its strength from the successive exposures to this high temperature. It may be laid down as a rule that better work will be done if it is done at a temperature not exceeding 300° by the mercury bath thermometer or 320° actual temperature. Of course more time is consumed in vulcanizing, but in these days, when heat regulators are almost universally employed to time the vulcanizer when in use, the extra time consumed is a small matter.

The occurrence of spongy vulcanite is always an indication that an excessive temperature has been employed in the vulcanizing process, and it will be better to lower it 15° or more, according to the thickness of the piece to be vulcanized. A slow raising of the temperature in coming to the vulcanizing point is recommended, but if the vulcanizing point is set low enough this will not be necessary, nor will the aggregate time employed in the vulcanizing process be increased.

To produce a thoroughly satisfactory and sanitary vulcanite denture, the vulcanizing process must be so conducted that there will be a constant pressure brought to bear upon the rubber as it vulcanizes, a sufficient quantity of it being present to insure the filling of the mold at the termination of the process, and to compensate for the shrinkage which inevitably occurs during the conversion of rubber compound of any kind into vulcanite. The pressure must be gradual and firm, and sufficient in amount to force the rubber against the

surfaces of the mold and teeth, and hold it in intimate contact therewith.

The vulcanizing temperature should not be above 300° by the mercury bath thermometer, this being 320° actual temperature; or if a thick mass of rubber must be vulcanized the temperature should be still lower. Rubber can be well vulcanized at a temperature as low as 265° as shown by the mercury bath thermometer. A flask should be allowed to cool very gradually, and should not be opened until it is at room temperature.

231 KENNEBEC AVE.

Dentistry After the War: A Promising Professional Field for Young Men.

By EDWIN N. KENT, D.M.D., Boston, Mass.,

PRESIDENT DENTAL HYGIENE COUNCIL OF MASSACHUSETTS; DIRECTOR OF EXTENSION LECTURES,
NATIONAL MOUTH HYGIENE ASSOCIATION.

THE industrial readjustment which will follow the present war will affect nearly all vocations to some extent for better or worse. The changed conditions will have the most marked influence on pursuits connected with manufacturing interests, and least in the professional fields.

One profession, however, will reap the benefits of a greatly increased demand, a demand which its present members must fall far short of meeting. Dentists may look forward to a season of unusual prosperity.

The cause is simply a matter of education. At the outbreak of the war the registered dentists in this country could properly care for but twenty million patients. Eighty per cent. of our people did not patronize dentists except for emergency service; did not demand proper dental treatment.

The situation was due, to some extent, to the expense of dental service, but it

was due to a much greater extent to the fact that a large majority of individuals have not realized or appreciated the value of a clean, unimpaired, healthy masticating organ in connection with the maintenance of systemic health.

The requirements of the present war have placed representatives from several million American households where they will live under rules and restrictions designed to build up strong bodies and develop physical efficiency. Compulsory dental service and education on the subject of mouth hygiene in the army and navy will impress upon enlisted men the importance of the dangers lurking in an unhealthy mouth, the functional inefficiency of a crippled grinding machine which cannot properly prepare food for the stomach, and the physically weakening influence of mouth neglect.

A large proportion of the eighty per cent. who were ignorant on the subject before they entered government service

will, on their return to civil life, continue to follow those habits of mouth cleanliness and care which they have been compelled to adopt, and this will necessitate regular visits to the dentist. A secondary result will come as the new idea is carried to several million American homes, where it will, in most instances, produce favorable results among other members of the family.

The present war furnishes, undoubtedly, the greatest opportunity that ever came to the dental profession to extend its field and its influence on public health.

Full advantage of the great opportunity will not be taken unless there are changes in Washington which cannot be reckoned on in the near future, but in spite of all obstacles, intentional or accidental, many millions of American people will be awakened during and after the war to a realization of the value of a healthy mouth, and with that awakening will come an unprecedented demand for dentists. To meet this demand the den-

tal profession must recruit new members.

The practice of dentistry does not offer any great financial returns. If a man's chief ambition in life is the accumulation of wealth he will be wise to direct his efforts into other fields.

But monetary considerations are not matters of paramount importance to a man with a sufficiently broad view of life to seek, in his selection of a life-work, a field where he has easy opportunity to put more into the world than he takes out of it. If there is one great lesson to come from the present war it is a broadened knowledge among men of the "blessings of service."

Dentistry offers to the young man whose talents run somewhat in the direction of mechanics and art, whose natural desires are toward doing with his own hands the things that he plans, and who will appreciate a field ripe with opportunities for public service, an ideal vocation.

158 NEWBURY ST.

CORRESPONDENCE

"A Case of Tooth Gemination."

TO THE EDITOR OF THE DENTAL COSMOS:

Sir,—On page 330 of the April number of the DENTAL COSMOS appears an article under the above caption. It is stated that the gemination is of the *lower central incisors*. Unfortunately, the illustrations accompanying the article make it impossible, for one who has not himself seen the case, to determine whether the gemination is that of the *centrals*. I am inclined to think that

upon careful examination it will be found that the union is with the lateral incisor of the same side, or with a supernumerary, one of the incisors having failed to erupt.

In teaching, I have always instructed my classes that such a union, across the median line, is never found.

Very truly yours,

LOUIS OTTOFY, D.D.S., M.D.

MANILA, P. I., June 13, 1918.

"Radiolucency of Chloro-percha in the Radiograph."

TO THE EDITOR OF THE DENTAL COSMOS:

Sir,—I desire to reply to the communication by Dr. Kells in the July issue of the DENTAL COSMOS.

I thoroughly respect the opinions and work of Dr. Kells and others who have disagreed with me in my previous findings as to the radiolucency of chloro-percha, and for that reason I have persisted in my laboratory experiments to find out wherein the difference existed.

I believe I have solved the problem, and will here so explain the result of my work that it will show we have *all* been right, yet there was one feature of the work that all of us have not known.

We will all agree that the reason for gutta-percha casting a more dense shadow than the tooth substance is due to the presence of lead oxid (PbO) in ordinary gutta-percha base-plate. This material averages about 25 to 30 per cent. of the different specimens I have examined.

I have made fresh chloroform solutions of gutta-percha base-plate, and found that the large root-canals filled as full as possible with the solution would not show in the radiograph more dense than the tooth substance. When further fillings were made from this same mix it would radiograph clearly, and continue to do so ever after.

I shall not take up your space by detailing the work necessary to prove the result, but give it to you briefly.

When the gutta-percha clippings are added to chloroform the chloroform removes from the base-plate the rubber

content, allowing the lead to precipitate to the bottom of the bottle. If this is not thoroughly shaken together the lead content is so low that the resulting solution will not show more dense than the root of the tooth. If this bottle is thoroughly shaken the lead is incorporated in the mixture to such an extent that the major portion will remain in suspense, becoming a part of each root-filling. It is then possible to get a sufficient amount in the canal to make it appear filled.

Some of my co-workers in the United States have gained the idea that I think it possible to fill a root-canal with chloro-percha. On the contrary, I have proved it to be entirely impossible.

Chloro-percha when mixed to a consistency possible of introduction into a canal shrinks $12/22$, therefore a root-canal filled with this solution is only $10/22$, or less than one-half, filled.

I therefore take the position that no root-canal has ever been one-half filled as to bulk and space in that portion wherein the gutta-percha point did not reach.

The reason why we have had partial success with this filling in the past is twofold: First, the tendency of chloro-percha to bridge at the apex, leaving the openings caused by shrinkage farther down the canal, and second, the few cases wherein aseptic conditions have been obtained and maintained in spite of the defective chloro-percha fillings.

Yours truly,

W. CLYDE DAVIS.

LINCOLN, NEBR., July 23, 1918.

PROCEEDINGS OF SOCIETIES

Dental Society of the State of New York.

Fiftieth Annual Meeting, held at Saratoga Springs, N. Y., June 13-15, 1918.

THE fiftieth annual meeting of the Dental Society of the State of New York was held in the Casino, at Saratoga Springs, N. Y., on June 13, 14, and 15, 1918.

THURSDAY—*Morning Session.*

The meeting was called to order by the president, Dr. Amos C. Rich of Saratoga, at 11 o'clock.

The living past presidents and Fellows of the society occupied seats on the platform.

Rev. PETER A. MACDONALD invoked divine blessings on the deliberations of the society.

In the unavoidable absence of the mayor, Judge McKELVIE of Saratoga welcomed the society to Saratoga Springs.

Dr. A. M. WRIGHT, Troy, N. Y., responded to the address of welcome on behalf of the society.

The vice-president, Dr. H. L. Wheeler, then took the chair, while President Rich read his annual address, as follows:

President's Address.

By AMOS C. RICH, D.D.S., Saratoga Springs.

OUR FIFTIETH ANNIVERSARY.

Fifty years have passed, and the Dental Society of the State of New York stands as a monument to the memory of those devoted and loyal members of the

profession who believed and worked to have it legally recognized as a profession. Among those who were active in preparation of the law, and who afterward became first president of the society, was Amos Westcott; singularly the name Amos is attached to that of the fiftieth president, but history will be unable to find any other parallel, because our first president, Amos Westcott of Syracuse, was a man renowned in his day and generation, being the man who discovered cohesive gold and the use of plaster for an impression of the mouth, thereby contributing to both operative and prosthetic dentistry. And it would seem that he was selected by the gods of destiny, as after events have proved and history hath recorded. He led and worked with a band of devoted and faithful workers, who builded the state edifice of Dentistry so well that it has stood the test of time. It seems to me superfluous that the record of our profession and of our society since its formation should be recorded in the President's address, because we shall be edified by a regularly appointed historian who is able and capable of making such a record. And further, we shall be permitted to listen to a prophet who may tell of what he can see in the future years before us as a profession.

In all probability few if any of those present at the formation thought of an anniversary meeting, much less a fiftieth celebration. But, ladies and gentlemen, we have with us today some who were

present at the birth of our society and have lived to see our profession attain its rightful status, and our society and state dental law become a criterion for others.

THE DENTAL PROFESSION AND THE WAR.

Since our last annual meeting we have a better knowledge concerning war and its awful frightfulness. We have been called upon to get closer to humanity and to help save it from becoming bestial, and before this war is over we shall be called upon to sacrifice much for humanity, victory, and peace. All in our professional work can help make men fit to fight—that life, love, and liberty may prevail. Each and every one of us may and should do his part. Some may go to the battle front, others to the camp front, others to the office front, and others can buy bonds and help our boys, Uncle Sam, and our gallant allies win the war. It is because of humanity and what we do for it that we are recognized as a profession. Our professional edifice has for its foundation humanity, otherwise we should be merely artificers or mechanics; therefore we should do much for humanity, especially at this time, when there is such need of our services to make those who go to the front fit to do their bit. It is not enough to buy bonds of Uncle Sam; that is a mere loan, and the best investment in the world. We who stay at home, whatever the cause, must do more, we must sacrifice in some way that we may be truly patriotic. If we cannot go to the front the least we can do professionally is to sacrifice our time and fees to make someone else fit by our skill. Then shall we feel true consciousness of having done real service for the flag we all love.

When the history of the war is written dentistry will be given due credit because we helped to make our fighting forces fit to face the enemy. History will show the unselfish purpose of our profession to serve humanity. That record will be one of glorious achievement, in restoring to friends and loved ones those who in fighting for liberty and democracy have been

horribly maimed and disfigured. Such scientific skill and prosthetic handiwork by dental surgeons and prosthetic artists has never previously been known or thought possible. Wonderful restorative work has been accomplished in conjunction with the plastic surgeons of the medical fraternity. It is manifest in the light of happenings of these days (quoting our lamented Dr. S. G. Perry, "In the fulfillment of our destiny, which is to be one of the most blessed because one of the most useful callings on earth") that a universal service must in the near future be an accomplished fact. As a nation we cannot go on in our present ways, knowing, as we do now, that we are not producing citizens physically nor mentally fit to fight for our rights. We face the failure side of our democracy as well as the other. We must provide ways and means to eliminate such failure. Our promiscuous population requires that drastic methods be employed to produce national and man power to protect our country, our flag, and our homes. We must not hereafter be content to ignore our failures because we are happy and prosperous as a nation. As physically perfect man power makes for victory and peace, so must the members of the fraternity of the healing art work to produce it, through universal service to humanity. Our citizens who are ignorant must be educated, that they may properly care for themselves and their families. In sequence it follows that those who are unfit to win their way, or fight to protect their country must be made so, then shall our country be better able to protect itself from those who would destroy us. Then may we eliminate disease, poverty, crime and aristocracy.

THE NEW DENTAL LAW.

The new dental law is working well, and thoroughly indicates the judgment of those responsible for its enactment. Many misgivings and much earnest solicitude was indulged in by some of our foremost thinkers concerning the provision which established dental hygienists. There is today much, and later must be more, gratification to us all that the

dental hygienists have established their worth and usefulness as shown by the records up to date. They will in the near future fill an important position in all offices where the practice is up to date, extending comfort to the patient and to the dentist under whose authority they operate. The demand for hygienists is now increasing, because they are legally recognized, and furthermore it has become evident to the busy practitioner that he can thereby be relieved of disagreeable drudgery. There is one portion of the law which should be heeded by all for the benefit of every ethical dentist, and that is the provision requesting each registered dentist to report to the secretary of the board of dental examiners the name of any person practicing dentistry who is not registered. In this connection every legally registered dentist should again read that part of the law which defines what constitutes the practice of dentistry. Please note that a sign or newspaper advertisement constitutes "holding out as practicing dentistry;" also note the provision regarding the practice of dentistry under *false* or *trade* name. Through annual registration we are able to locate every person practicing dentistry legally; that is, if everyone registered does his duty toward his fellow practitioner and himself. Remember the name of the informer is held inviolate. Information regarding illegal practitioners helps to enforce the law. All must remember that no one man can be in all parts of the state at the same time. The prosecuting officer representing the profession must have the assistance and co-operation of all.

THE PREPAREDNESS LEAGUE.

This war has driven many things from our minds, but we must continually promote and enunciate the necessity for and means to national health. Greater co-operation with and greater manifest interest in the work of the Preparedness League of American Dentists are desirable, and much greater participation in its activities. We may not all agree with the methods nor with those who are active in the work of the League, but we can

and must all agree that the fundamental principles of the League's activities are sound and necessary, and furthermore, it cannot hurt but must rather amplify our usefulness as a profession. The League now has a membership of over 15,000, and has a complete organization in each state, in Alaska, and in Porto Rico. It is connected with the general medical board through a subcommittee of the committee on dentistry of that board. It has the indorsement of the Government because of its assistance through dental service to drafted men. The dental motor car of the League is probably the most perfect of its kind in the world, and is a marvel of ingenuity. Its capacity is about 100 patients a day, and its cost about \$5500. The League is certainly one of the most potent unifying influences in the dental profession today. And to my mind there is no need of its work or influence being lost whenever the war shall cease; it is dedicated to the service of the greatest flag that floats.

PUBLICATION OF THE SOCIETY PROCEEDINGS.

In the interest of true professionalism I again recall to your mind the publication of our proceedings as a State Society. For some years they have been published by a trade journal at their convenience and for their advantage, because of the merit of the material produced, otherwise a trade journal would have no use for it. True, they are so published at a nominal cost; nevertheless at a high cost to us in a professional sense.

Professionally it is no incentive to members or guests who appear before us as essayists or discussers to have their efforts subjected to the whims of a trade journal editor, as to what is worthy or eligible, and likewise as to the proper time for publication. As members of a society of professional men (which means that we stand before the people better educated and worthy of trust as practitioners of our branch of the healing art) we should desire better things concerning our proceedings and their publication. We have had unnecessary and unfortunate experiences regarding this matter, and a society with fifty years of

professional and scientific work already accomplished should not relinquish control of the professional and scientific material brought before it, and for the production of which it is responsible. Our membership should not be compelled to await the disposition of a publisher as to the proper time of publication before they can avail themselves of the professional and scientific data therein contained. We really should adopt and maintain a higher standard for the platform upon which we stand. I therefore recommend that necessary action be taken to publish our proceedings under conditions of society and professional control. Furthermore, in my humble judgment the dental profession must soon assume an advanced position as regards publicity of professional knowledge for the benefit of the people. Our State Society as the representative authority of the dental profession in the state should be responsible for the better education of the people concerning dentistry. It should not be left to any unauthorized person to go before the people to give publicity to his personal views as to what is best procedure in dentistry. I sincerely hope this society will give this matter sincere and careful thought and study, to the end that we may in the near future have a real publicity department.

MEMBERSHIP.

It is wise to take a perspective view of ourselves at times, and with that in mind let us investigate our membership. Today there are about 5600 practitioners of dentistry within our state, and as our total membership is only 1400 we do not numerically represent our profession. In numbers there is strength. We should be a strong society in that sense. Legally we are strong. We, as a profession in this state, could do great things with large increase in membership and the consequent increase in financial help. With the assistance of the published list of registered dentists in the state issued each year according to law, the members of our State and district societies can with little effort eliminate from the reg-

istry list all but the ethical practitioners; then, by comparison of the ethical with the membership lists, the eligible dentists could be listed and a great increase in membership could be accomplished by systematic work through energetic committees. It is only necessary for me to refer you to the very great increase in the membership of the Ninth district, who have just emerged from this year's membership campaign with a 50 per cent. increase, to show what can be done by united effort and systematic work. A few years ago our membership was augmented by changes in the constitution and by-laws regarding membership, and when we observe what has been done through efforts made at that time and the effect upon our State Society, what may we not expect from a much larger number of members such as we can have by a little effort on the part of those within? We should benefit ourselves, our profession, and humanity. Therefore I recommend that there be appointed a membership committee of one or more from each district society (with power to increase the number) who shall be charged with the duty of increasing their membership. It might be wise to offer some inducement to instil rivalry as to which district should make the greater percentage of gain according to its present memberssipp.

PUBLICATION OF A SOCIETY BULLETIN.

I am very strongly of the opinion that our State Society is greatly in need of the assistance that will be afforded by an official *Bulletin*. It is not necessary that it be an expense, it can be made a source of revenue. It should be a means of communication between the district societies as well as between the State and district societies, and last but not least, it is a means whereby the officers and committees can communicate with the members, and official announcements can be made. I refer you to the successful use of a *Bulletin* by the Second and Ninth districts. Our society cannot stand still, we would disintegrate. We must progress. We should be a *live* society. Everybody likes to be a part of a live organization,

and I believe a *Bulletin* to be one of the means of producing a going society. I therefore recommend that action be taken favorable to the early establishment of the State Society *Bulletin*.

APPOINTMENT BY THE STATE OF AN ORAL HYGIENE INSPECTOR.

I am informed that there was inserted into the budget of the state Educational department the sum of \$3000 for the oral hygiene purposes this year, providing for an oral hygiene inspector to be attached to the school medical inspection department. It may be permissible for the Oral Hygiene Committee of our society to co-operate in this work, which so essentially pertains to our profession. I therefore recommend that a contingent appropriation be made for the Oral Hygiene Committee, and that they be instructed to investigate, and if co-operation with the Educational department be possible, they may be in a position to do so.

There has been and is now being agitated by old and new organizations in the United States the subject of improvement in the physical conditions of male citizens of the country. The disgraceful physical conditions of our man power as shown in the defects disclosed by the examinations of our volunteer, enlisted, and drafted men to form the national army are such as call for laws and regulations that will compel a physically strong American nation. Just what the best means are to bring about such a condition should be found by representatives of the medical and dental professions. It must be a patriotic duty with us so to rear our children that they may become mentally, morally, and physically fit to fight if need be for our national rights as a democracy. To this end it would seem to me pertinent that the State Society should memorialize the National Dental Association upon a propaganda for universal service and preparedness through national physical standards and other agencies, and the means to attain them.

Permit me to express my hearty appreciation of and my sincere thanks for the

work done through the year by the officers and committee members and guests, and all others who in any way have contributed to the success of this celebration. For to them is due all credit. Much credit must be given the clinicians who have consented to interpret the vital operations they have brought to our attention. The hearty co-operation of the manufacturers and exhibitors in helping to make this meeting a success is most heartily appreciated.

I have visited every district society where invited with the exception of one, that omission being unavoidable. All the pleasures of this office come from personal contact with the membership at these gatherings, where hospitality and good cheer prevail. I feel greatly indebted for such hospitality extended to me during the year.

It will be the gratification of a sincere wish if all who attend this meeting shall have a pleasant time, and go away feeling that they have been rewarded for coming.

Dr. WHEELER. The address is referred to the standing Committee on the President's Address, which will report at a later session.

President Rich then resumed the chair.

Dr. WILLIAM CARR of New York, read a paper entitled "History of the Dental Society of the State of New York."

[This paper is printed in full at page 193 of the present issue of the *Cosmos*.]

The President then called upon Dr. J. W. Beach of Buffalo to speak on behalf of the Preparedness League of American Dentists.

Dr. J. W. BEACH, Buffalo. This is an unexpected pleasure, but we can always say something about the Preparedness League, although I can tell very little that will be new. The work has been going on since war was declared in this country, and about fourteen months prior to that, to take care of the draftee and make him dentally fit to go into the fighting line.

Prior to the declaration of war the work was confined to the National Guard,

and a great number of operations were performed, prior to the active work of the League after war was declared.

In August 1917, the proposition was made to the Surgeon-general that we take up the work of preparing these men in the eastern military department. This was given to the charge of Major Heckard and Dr. Ash, who kindly assumed the responsibility. They appointed directors in different parts of the division, and started work which went on so well that we eventually asked for the whole United States. It was rather a large request, but it was granted us. Then the work of organization proceeded from the New York headquarters, under the direction of these two gentlemen, and a wonderful organization has resulted. It may be new to you to know that each week, for the last six weeks at least, we have received at those headquarters 10,000 cards, each one of which says, "This man is dentally fit to go into the fighting line." This has cost the government nothing, except the salary of the one military representative, Major Heckard.

We feel the work has now reached a point where the dentists of the country may feel that it is properly approved. The government officials have backed up the League in a wonderful way, and I wish I could tell you all I would like to in that respect; but it has been because 15,000 dentists have banded together in this work, and have said to the League that they would give one hour free dental service each day, and would make these men dentally fit for service.

There has been misunderstanding as to the actual status of the registrant in regard to receiving free dental service.

First, I may say we want it particularly well understood that every service rendered in the name of the League must be done absolutely without fee. Even if a man presents himself who is well able to pay that fee, we do not question him whatsoever. If he wishes one hour service, which the League asks shall be given him, he is entirely welcome to it. Beyond that time, if the dentist feels he should not give that man further free service—and we do not mean to interfere

with the regular practice of any dentist—if that registrant says he can pay for that service, he should then be discharged as receiving the benefits of the League, and either sent to another dentist or, if he wishes to have the dentist continue his work, he may apply in the regular way to that dentist. The card which is then filled out—Form 3-c—is put in the mail, and the service to the registrant ends there. It is the opinion of those higher than the authority of the League that this service must be rendered in this way without any question whatever.

We want the public to understand that the League is in no wise a part of the government. It is merely sanctioned and approved by the government. The men who apply to us for free dental service have the impression that the government is to pay for this work, and we would like a certain form of publicity to go out correcting that idea. If the public understands this, I believe it will help very much in correcting many misunderstandings. We have those who perhaps wilfully bring up points which rather interfere with the smooth running of the League in that way, but the great object we wish to impress is that it is for our country, for our men, and for our profession. We must make our men as well prepared as possible to undergo the hardships which they will encounter on the other side. We cannot sidestep this issue, and in view of the fact that the League is the only organization which is undertaking this specific work, we should take it up as far as we can, and understand we are the only ones who can perform this service. Anyone can carry a gun, but all cannot do this work. A child can sell war savings stamps and sell Liberty bonds, and take Red Cross contributions. I feel that our professional men should therefore confine their efforts to doing the things which others cannot do. There is not a man here who can in any sense serve his country so well by carrying a gun on his shoulder as he can by filling teeth. Those are a few points we would like understood by our members.

I personally am very deeply imbued

with the feeling that we should inaugurate a simple, practical study course, if you wish to put it that way, or a course of instruction for the lay practitioner. The government is preparing in every way to fit our reserve corps men and regular army dental surgeons to take care of the men when they return injured. That leaves out of the reckoning a man who is taking care of the civil practice. This man should have the benefit of some instruction that will help him to take care of the cases which will

return, and which the government cannot take care of, or cases which have slipped past the government officials. We must be prepared to take care of the men who come back injured, and we are trying to formulate a simple, practical course which can be given for these men. I feel sure we have the full co-operation of the dental profession.

The society then adjourned until 2 P.M.

(To be continued.)

Connecticut State Dental Association.

Fifty-fourth Annual Convention, held at New Haven, April 18-20, 1918.

THE fifty-fourth annual meeting of the Connecticut State Dental Association was held at the Hotel Taft, New Haven, Conn., on Thursday, Friday, and Saturday, April 18, 19, and 20, 1918.

THURSDAY—*Morning Session.*

The meeting was called to order by the president, Dr. Elwyn R. Bryant of New Haven, at 11.30 o'clock.

The first order of business was the reading of the minutes of the previous annual session.

Dr. S. L. BECKWITH-EWALL, Hartford, moved that in view of the fact that the minutes had been published by courtesy of the DENTAL COSMOS, the reading thereof be dispensed with. (Motion carried.)

Dr. FRANK J. BUCHANAN, Waterbury, read his report as treasurer.

Dr. B. A. SEARS, Hartford, moved that the same be accepted, and referred to the Executive Committee. (Motion carried.)

The next order of business was the report of the Executive Committee, by Dr.

MORTON J. LOEB, New Haven, chairman, as follows:

The Executive Committee is not able to report on the Treasurer's Report at this time, because the balance of the committee has only come here within the last hour. It should be gone over, and we will report at the Saturday meeting.

The committee has purchased four dental chairs, three new ones and one slightly used. It was the purpose of the society to purchase two each year. Last year we could not get any, so this year we purchased four.

The committee wishes to announce that for patriotic reasons it relinquishes the ballroom, where we are to hold our meetings, until about 4 o'clock. Secretary Daniels of the Navy, is here, and the New Haven Chamber of Commerce will give a luncheon at 12.30, when the Secretary will speak.

The Executive Committee arranged for the rental of the ballroom and foyer at a cost of \$120 for three days, and an additional cost of \$5 per room, per day, for the extra rooms on the tenth floor. We feel the hotel made every conceivable inducement to us to come here, and they have been most courteous in their treatment.

On motion, the report was accepted.

Dr. E. S. GAYLORD, chairman of the Committee on Necrology, presented the following report for his committee:

REPORT OF THE COMMITTEE ON NECROLOGY.

Until this morning, I hoped to be able to make the same report as last year—that we had lost no member; but in my morning mail I received the announcements of the deaths of Dr. Charles Burns Erichson of New Britain, and of Dr. William French Gerrish, of Bridgeport.

On motion, the report was accepted.

Dr. Geo. S. B. LEONARD, Mystic, presented the following from the Board of Censors:

REPORT OF THE BOARD OF CENSORS.

The Board of Censors, during the year, have held five meetings, and there are now 399 active members in good standing in the association. There are seven honorary members. We have received to date about thirty new applications for membership. We expect only six to be dropped for non-payment of dues. The total of active members will be about 421.

The report of the Committee on By-Laws was presented by Dr. E. S. GAYLORD, chairman, as follows:

REPORT OF THE COMMITTEE ON BY-LAWS.

We have presented something in the form of a revision of the Constitution and By-laws. For various reasons, we have delayed this and have been excused, but this year we have sent to each member a copy of the proposed by-laws. That is subject to your approval, and is presented with the anticipation that it will be received cordially.

Dr. SEARS. I move that the proposed revised constitution and by-laws be taken up by articles—the secretary reading each article, and the association acting on each individually. (Motion carried.)

The first three articles of the constitution were read and adopted.

Dr. CROSBY moved to adjourn at this time, on account of the Chamber of Commerce banquet to Secretary Daniels, to which some of the members were invited.

The society then adjourned until 2.30 o'clock.

THURSDAY—*Afternoon Session.*

President Bryant called the meeting to order at 2.30 o'clock.

Major HOWARD A. GIDDINGS of Hartford spoke in the interests of the Third Liberty Loan, and related many interesting facts from his experiences "over there."

A vote of thanks was tendered to Major Giddings for his interesting talk.

Dr. NORMAN B. NESBETT of Boston, Mass., gave a presentation of "A Simple Method of Supplying Posterior Teeth, Using Cast Clasps." [The substance of this paper was published in the DENTAL COSMOS for March 1918, page 204.—ED.]

The next item on the program was the reading of a paper by Dr. FRANK A. DELABARRE, Boston, Mass., entitled "The Diagnosis of Malocclusion in Its Early Stages."

[This paper is printed in full at page 789 of the present issue of the COSMOS.]

DISCUSSION.

Dr. E. A. Bogue, New York. I have been greatly interested in Dr. Delabarre's presentation, and as he was kind enough to ask me to discuss the paper and perhaps criticize a little, I felt pleased and honored that your president seconded the request.

In the first place, I suppose I am speaking not to orthodontists, but to general practitioners. It has never been my own view that orthodontia should be practiced exclusively by a class of men who declined to acknowledge that they were dentists. I am a dentist and have always been such, ever since I undertook to do anything for a living, and I think I rather glory in it. Dr. Delabarre referred to the curve of Spee. How many of us understand what that curve of Spee is? Spence Bate of England was my guest in Paris once for dinner. He is

a member of the Royal Society. He, although a dentist, was one of the naturalists who were requested to examine the finds of the "Challenger," sent out many years ago exploring for the museum.

He said to Dr. Davenport and myself that the level of the grinding teeth in the human mouth was practically along a straight line. We both denied that, as politely as we could, but he insisted that he had published a number of books and illustrations, and indicated where we would find them in England, and invariably he had made that line of articulation between upper and lower teeth a straight line.

Our friend Spee many years after that discovered and wrote up the curve which takes place when the mandible develops sufficiently. Our friend Bate—at that time about forty-five years of age—did not know that that curve existed.

I speak of that because Dr. Delabarre has taken it for granted that we all know what that curve is.

I want my fellow practitioners of dentistry also to know that the need for early diagnosis of impending irregularities not only exists, but it is quite possible to diagnose those cases a long while before the permanent teeth erupt. I am glad that the preventive idea alluded to by Dr. Delabarre has been established in Boston, for in the section where I live, some of us are still waiting for the permanent teeth to appear before any steps are taken to assure regularity, and the tendency of most orthodontists is to counsel waiting. I cannot myself see any just grounds for that.

I found at the Health exposition in Dresden that the brain of the newborn child weighed 371 gms. at birth, as an average; and I noticed that the brain of the child at six years weighed 1360 gms. I noticed further at that same exposition that the brain of a person of nineteen years weighed 1400 gms. The gain between six years and nineteen years is but 40 gms. in weight—I speak of the average gain—while the gain between birth and six years is enormous. I cannot give it to you from memory.

What is the teaching that we may draw from that? It has been noticed in my own office that most children up to six or seven years of age have a quickness of perception and a power of reasoning that fits them to understand the corrective measures that are being taken in their behalf, and makes them in most instances efficient helpers; while children taken later than that age seldom grasp the situation or its details, and are as apt to place themselves in opposition to our wishes as they are to be helpful. Hence the percentage of successful cases begun before the expiration of the sixth year, I should think would be about 99 per cent.; but from the sixth year to the thirteenth year I think it would depend upon the intelligence, patience, self-denial, and Christian fortitude of the operator—to say nothing of the endurance of the mother—whether we had any successful cases or not.

Dr. Delabarre says malocclusion is seldom a local disturbance, more often a local symptom of larger or more remote causes, producing results elsewhere. Quite right. And now I wish to make my grateful acknowledgments to him for having referred to my great trouble in learning how and when to diagnose these cases. And as I possess, I think, the largest number of models of cases reaching back into the past, of anyone I know of—although those models may not be very perfect, I think the teeth are sufficiently so to judge from—I find that no case that does not exceed the 28 mm. in breadth between the palatal edges of the second deciduous molars is ever able to develop normally. I find there is a physical weakness that interferes, and there is where we come in as practitioners of the science of medicine, and where our teachings—I think I am justified in using that word—to the medical practitioner may be of help to him. The medical practitioner sees these children long before we do, and he can with perfect ease, using a little millimetric measure, at once—in two or three seconds—test the width of the arch between the second upper deciduous molars any time after the complete eruption of the deciduous

teeth. This occurs at two and a half to three years of age, and from that time until the time the permanent teeth begin to erupt, at about six years or later, these measurements can be taken; and we should, I think, instruct him that when he finds no greater width than 28 mm. it is time to call in the dentist, or, if he prefers, an orthodontist, if there is no dentist who is qualified along those lines. He will also find in more than half the cases of impending irregularity a curvature of the spine, more or less pronounced.

I happen to have in my satchel now the model of a little girl, the daughter of a dentist, who took an impression of the little girl's mouth at two years and ten months. I never saw the child until last week. She is now six and a half years old. I said to her father, who had given me this first model to look at, "You will find that child has not grown laterally at all." "What!" said he, "in all those years!" I said, "No, sir, not at all." He brought in the child, models were made, and there is no growth. The father has asked that the arch be spread. There is just time to do it, but I think the gentleman was very much surprised to find there was not a hair's breadth of growth in all those years.

A physician was sent to me with his two children some years ago. I took impressions and made models, and advised spreading the arch; but nothing was done; three years passed. He came again, and brought his two children. Impressions were taken, models were made, and nothing was done; three years more passed. He came again, and this time brought three children. Impressions were taken, models made, and nothing done; but an appointment was made with my then assistant, Dr. McKnight, to go on with the older daughter. Before that appointment could be kept the father telephoned me that that daughter was in an asylum, and he had received word she would never recover her mind.

I received a hint then and there not to mention that in this connection. I have violated the hint for this reason: Some years ago Dr. Lawrence Baker ground off

the teeth of three rabbits out of a litter of five. You are all familiar with the experiment, which resulted in mastication being done on one side of those rabbits' mouths. The whole litter of rabbits was simultaneously killed, and their skulls examined, and all that side of the head which had been deformed by grinding off the teeth was found to be smaller than the other side. That experiment, in substance, was repeated by a gentleman in Berlin University, who removed the germs of teeth from some puppies. The mutilated sides of those heads were all smaller, owing to interference with the proper performance of function.

Dr. G. V. I. Brown did the same mutilation practically some years ago, again with the same results. We do know that the size of the brain has to do with the intelligence of the owner of that brain. We suspect it has something to do with it, but the convolutions of that brain have more to do with it. Yet when we find the size of the brain-case diminished by failure to masticate, and failure of the muscles to exert their specific influence in regard to the growth of the bone, we find there has been a diminution in the necessary vital force which should have brought these animals—whether two-legged or four-legged—to completion.

Therefore I most heartily second Dr. Delabarre's conclusion and hope we will all make it our duty to examine carefully into the width of the dental arches of growing children, to see whether or not prevention is not a great deal better than subsequent cure.

Dr. F. L. Stanton, New York. I think this is a very important topic for general practitioners. It has come late in our professional life, because the evolution of dentistry has been upside down. The first dentists were thinking of substituting artificial substitutes; then they thought of patching teeth, and then holding pyorrheal teeth in the mouth, but they did not think of doing this preventive work which is engaging our attention now. I think this is a most important paper, and one that should be taken home with all of us, because if Dr. Dela-

barre is right, and there are 90 per cent. of the children in your practice at six years who need this treatment, you should familiarize yourselves with the diagnostic signs. The only thing I can add to this paper is to emphasize a way in which you can more forcibly impress upon the patient the need of this treatment.

Dr. Bogue's idea of the 28 mm. is fine, but you want to be very careful you are on the right side.

In order to impress upon you a diagnostic sign, if you will take this chart, you will realize that these three teeth (indicating) are fully as wide as the three permanent teeth that will follow. Explain that to the patient's parent. If that space is wide enough, you will have plenty of space for the cuspid. You will then have to have space for the four teeth. You can say to the parent of the patient, "Unless you have space here, you cannot get a 7-mm. tooth in here. A small central is 8 mm., so if you have no space between the deciduous teeth, you will have an arch that is too small."

I understood Dr. Delabarre to say in referring to Fig. 5, there is good occlusion and a good curve, yet the median lines did not correspond. It would be a physical impossibility, if you had two curvatures that are good, it would be a physical impossibility to have two good dimensions, and not the third. However, that is splitting hairs. The idea you want to get at is that the parents should be taught this.

What is the deviation from the normal? What is the normal for this patient? Now that you have pointed out to your patient that there is an impending malocclusion here, how does Dr. Delabarre explain to the patient what he is going to do? What are you going to do, after you have advised the patient that that malocclusion needs treatment?

Dr. F. T. Murlless, Hartford. There are two things I wanted to say. One is, I think Dr. Bogue has rather overstated his attitude in regard to dentistry. I think I might say in truth that orthodontia (I am speaking for myself indi-

vidually) has made better dentists of us, and I think we are proud of the fact that we are better dentists. In observing my friends who are orthodontists I feel sure, from my acquaintance with them before and since they have taken their courses in orthodontia, that they are better dentists.

Dr. Delabarre (closing the discussion). It is significant to think over those figures Dr. Bogue gave you in regard to the growth of the brain. I cannot give it to you stated in percentages, but you can see that the child's brain attains almost its full weight at the age of six. It is also a fact that the width across the deciduous arch in the bicuspid region has been fully attained long before the bicuspid come to supplant the deciduous molars. Once attained, there is no further growth in that region, so it is important that this width should be secured for the child when the width is due to come, and not later.

Dr. Stanton spoke of the difference in the measurements of deciduous and permanent incisors. Black's figures are not absolutely dependable, because they are taken from indiscriminate teeth, and not teeth taken from sets; but it shows there must be a growth of 7.6 mm. between the upper deciduous cuspids in order to accommodate the permanent incisors; and in the lower, the growth necessary is 6 mm.

With regard to Dr. Stanton's criticism of my explanation of Fig. 5, where I said you have a deviation in the lower and upper incisal median line—you may have that alone without any of the other complications. What I meant was this: From your examination of the child in the chair, you could see no disturbance of the arch curve as such. If you look at one model without making a critical examination, it might appear to you to be a good, normal curvature; but the deviation in the arch curvature—the lateral asymmetry—will appear only upon very careful examination.

I have purposely confined this paper to the subject—the diagnosis of malocclusion in its early stages—and made no attempt to go into the question of causa-

tion or anything else. I simply wanted to present these seven diagnostic signs so you may apply them in your practice, and give the parents of those children the proper advice, and be able to answer their question, "Has my child crooked teeth?"

Dr. Bogue. Some years ago a lady quizzed me extensively before she would allow her children to come into my hands. She finally brought them, and after I had had them several years, in 1894 I requested permission to take impressions of the mouth of her little girl then four years of age. Permission was granted, and I took them. At that moment, after I had made my model, I said to the mother, "I think if you will examine a baby's skull, at six years of age, from which the anterior plates of bone have been removed so as to show both deciduous teeth roots and the crowns of permanent teeth, you will agree with me that if I can find distinct irregularities in your little girl's teeth, we are safest in moving those deciduous teeth now to where we think they ought to be." She gave permission to move them.

It is evident to every one of my professional brethren who hears me at this moment that I was risking my whole practice—I was risking my professional life—on the correctness of my diagnosis. I would only add that it proved to be so correct that from that day—I began my correction in 1898-99—to this, I have carried that correction forward. Those first children, I am proud and happy to say, are still with me as patients. Several others have been, but I never again shall fail to sustain Dr. Delabarre in his contention that we all owe as a duty to our patients the early detection and prompt correction of the impending

irregularities which we are perfectly able to detect at a very early age.

The meeting then adjourned to 8 P.M.

THURSDAY—*Evening Session.*

The meeting was called to order by President Bryant at 8.30 o'clock.

Dr. M. J. LOEB, New Haven. It is customary to give each man who occupies the president's chair of this association some slight token of appreciation from the members. I am in a position this year to say that no man is more deserving of that honor than the present incumbent of the office. I have worked with him for more than two years, and it has been a pleasure to see the interest he has taken in the society.

It is with a great deal of pleasure, Dr. Bryant, that I present this gavel to you on behalf of the association.

The PRESIDENT. All I can say is, I thank you. I will try to use it to advantage.

Dr. PERCY R. HOWE of Boston, Mass., gave an address entitled "Some Ideas in Regard to Root-canal Work." The address was illustrated by lantern slides and chemical tests.

Dr. LEONARD moved a vote of thanks to Dr. Howe for his most interesting and instructive address. (Motion carried unanimously.)

Mr. IRVING L. BROWN addressed the members on behalf of the Dentists' Mutual Alliance.

The meeting then adjourned.

(To be continued.)

THE DENTAL COSMOS

A MONTHLY RECORD OF DENTAL SCIENCE.

Devoted to the Interests of the Profession.

EDWARD C. KIRK, D.D.S., Sc.D., LL.D., *Editor.*

PHILADELPHIA, SEPTEMBER 1918.

EDITORIAL DEPARTMENT

Co-operation in Scientific Research.

At the recent thirty-fourth annual convention of the American Institute of Electrical Engineers, the president, Mr. E. W. Rice, Jr., who is also president of the General Electric Company, in his annual address, briefly referred as follows to the time and attention which had been devoted by electrical engineers to the solution of many war problems:

A work which has caused means for the detection of the pirate submarine; wireless signaling and telephoning for army and navy, and aircraft devices; searchlights of novel design and great power; improved methods in the manufacture of ammunition and ordnance; electro-chemical work of every description; electric welding; X-ray sets of greater simplicity, and many other lines too numerous to mention.

As contributory factors to the gratifying results attained in the lines referred to, he states that

The great industrial research laboratories, the educational and governmental research departments, have all co-operated enthusiastically and effectively, and the members and their staffs have labored day and night, without regard to pecuniary reward or public applause, sustained entirely by the high purpose of giving their best to the service of the country. I hope the time may come when the story may be told, so that the world may realize the debt which it owes to scientific men and engineers, without whose arduous, unselfish, and almost inspired work, our cause, righteous as it is, would have no chance for a victorious conclusion.

The foregoing statement, made by one so well qualified to speak with the authority begotten of wide knowledge of his subject and a broad view of human affairs, is both interesting and important; interesting because it is a picture of large things effectively done, and important by reason of its revelation of the means and the spirit by which the achievement was made possible. The winning of the war has demanded from everyone in the Allied cause the highest type of service of which he is capable, and the utmost promptness and efficiency in its rendering. The creative faculties of the nation and its limits of resourcefulness in manpower, in material and intellectual efficiency, are commandeered by the Government in the national service, and it is the harmonious co-operation of these resources that will eventuate in making the world safe for democracy and a decent place in which to live.

What has been done in electrical engineering is an index of what is taking place in all branches of human endeavor, but what is particularly striking in the reference we have quoted from President Rice's address is the co-operative element in and among the great industrial, educational, and governmental scientific research laboratories that has made possible the important electrical engineering developments which he specifies. Never before has there been so strenuous, so insistent a demand upon applied science for the solution of practical problems as the present war necessity has created, and in the effort to meet this demand the development of practical results has been correspondingly rapid and fruitful.

To achieve the results already attained there has been a notable and praiseworthy breaking down of barriers that in ante-bellum times were obstacles to scientific development in its practical applications. Problems wrought out and discoveries made in industrial research laboratories were safeguarded as the bases of commercial enterprises, and in a similar way much work done even in

educational institutions was monopolized or protected by patent right for individual gain. The necessities of the nation at war are inculcating a broader outlook and more altruistic spirit, so that co-operation for the common weal is coming to be the keynote of individual effort.

Dentistry has made for itself an enviable record in the way it has responded to the Government requirement for its specialized service in the war emergency. But we shall have failed of reaching the full measure of good to the profession of dentistry itself in the giving of that service if we fail to take cognizance of and to practically realize the new ideals and larger purposes which the war experience is developing in allied lines of activity. Of fundamental importance is the co-operative spirit among scientific activities in industrial, educational, and governmental research laboratories as noted by President Rice.

We clearly realize the crying need in dentistry for scientific research in the solution of an endless variety of problems that we deal with wholly empirically at present. A praiseworthy beginning has already been made toward a research foundation by the National Dental Association, but much more is needed if dentistry is to be placed upon a practically sound scientific basis. First and most important is the need for the same spirit of co-operation among the dental scientific research laboratories already established as that noted by President Rice as now existing among the research laboratories more particularly concerned with electrical engineering problems. The time is passing when dental research laboratories, even those connected with the large dental industrial enterprises, can be conducted wholly for commercial gain. No individual or corporation can rightfully control scientific research, and, as a practical matter of fact, those things which were formerly regarded as "trade secrets" quickly become common knowledge, so that the tendency is toward a broader view of these questions, for the spirit of the time tends toward interchange of ideas and practical co-operation in those lines of endeavor concerned with scientific development even among industrial enterprises.

We have to suggest, in view of the foregoing, a survey of the existing resources of dentistry with respect to scientific research, and their co-ordination for the good of the whole profession. In principle we believe the suggestion to be right. Its

practical application would economize effort by avoiding repetition of work and the re-discovery of known facts, and would bring to light and into general usefulness much important matter which is not now utilized because it is not recognized. Most of all there is needed competent, broadminded, and unselfish leadership to make the suggested plan effective; but where the way is clear, leadership will come.

The Greene Vardiman Black Memorial.

THERE could have been no more fitting climax to probably the largest meeting that the National Dental Association has ever held than the dedication of the memorial statue (see Frontispiece) to Dr. G. V. Black, which took place on Thursday afternoon, August 8th, at the time of the National meeting, in Lincoln Park, Chicago, in commemoration of the lifework of Dr. Black.

Thursday noon a luncheon was given by the Association to the past presidents of the American Dental Association, the Southern Dental Association, and the National Dental Association, at which time Dr. A. W. Thornton of Montreal, Canada, paid a glowing tribute to the memory of Dr. Black, and immediately thereafter the audience reassembled in Lincoln Park, where the formal unveiling and dedication of the memorial monument took place.

Dr. C. N. Johnson, a lifelong friend and co-worker with Dr. Black, presided as master of ceremonies, introducing the various speakers who took part in the exercises. Dr. Truman W. Brophy presented the monument to the Lincoln Park Board of Commissioners, with a brief history of the movement which culminated in the erection of the memorial to Dr. Black. The principal address was delivered by Dr. Thomas L. Gilmer, an intimate friend and close professional associate of Dr. Black, in which he recounted the works of Dr. Black and recited many interesting personal reminiscences of his professional career. The monument was unveiled by four little granddaughters of Dr. Black, Misses Elizabeth Black, Mary Barbara Black, Jane Black, and Helen Baldwin.

Coinciding as it did with the sixtieth anniversary of nationally organized dentistry, it was peculiarly appropriate that the dedi-

cation should take place at the same time, for Dr. Black's life-work was coeval with the development of dentistry into a profession. When Dr. Black entered dentistry it was in a chaotic and unsettled state, and it was due to the activities of Dr. Black and men of his type that an organized scientific profession was evolved from what was previously an empirical vocation.

Dr. Black's was a distinctly scientific mind, and from the time of his entrance into the profession he began to devote his energies to the standardizing of instruments, materials, and methods of practice, and it was not long before the profession began to reap the benefits of his valuable work. Without doubt Dr. Black's investigations and studies were directly responsible for the high state of perfection that has been attained in the manufacture of dental alloys; and in the field of Operative Dentistry his name will always be revered as the benefactor of the profession for having developed a definite, scientific method of procedure for cavity preparation in carious teeth. The limitations of space will not permit the recounting of the many benefactions which Dr. Black's work conferred upon dentistry, but the above will serve as conspicuous examples from a life whose constant aim was for the betterment of his fellowmen and one characterized by an unswerving devotion to the profession which he chose as his sphere.

Dr. Black was deeply interested in the development of dental education, and as the result of his activities in this field of labor his name is inseparably associated with every advance in dental education made during the sixty years of his association with dentistry.

Those who were fortunate enough to be present and observe the Black Historical Exhibit at the National meeting under the supervision of Dr. William Bebb gained some conception of the stupendous amount of work done by Dr. Black, not only in dentistry, but in other fields of science and art. His literary activities were not confined to dentistry, but his breadth of mind and knowledge showed its diversity in numerous subjects not particularly related to his professional work. In the exhibit above referred to were the original manuscripts of treatises by him on such subjects as "The Wasp," "The Seventeen-year Locust," "The Earthworm," "Tornadoes," "Fossil Woods," "The Use of Books," "Mechanic Arts," "Morality," "The Theory of Sight," "Our Police

System," "Indian Stories," etc., ample proof of a versatility that is possessed by few men in any walk of life.

Dr. Black's was a conspicuous exception to the fate of most great men, in that during his lifetime he was the recipient of almost every honor that could come to one in the dental profession, and this handsome memorial statue is but the crowning honor to a life that merited and received full and ample recognition of its greatness.

Transactions of the Inter-Allied Dental Congress.

IN our June issue we published a review of the above report of the proceedings of the Dental Congress of Allies held in Paris in 1917 under the patronage of the French Government.

The report is a remarkable exposition of oral surgery as applied to injuries of the face and mouth occurring in the present war, and comprises many valuable contributions from the leading men of Europe in this branch of surgery.

On account of the present war conditions the cost of producing these Transactions has necessarily been large, and the Secretary-general has requested us to give the fact that they are now ready as much publicity as possible, to the end that a sufficient number of subscriptions may be received to defray the expenses of publication. The report comprises two large volumes of 1600 pages, profusely illustrated with 1100 half-tones. The price is 30 francs (approximately \$6.00), exclusive of postage.

We heartily commend the work to every dental surgeon as the most comprehensive compilation of oral war surgery that has appeared in our literature, and one that will without doubt prove very valuable to everyone interested in war surgery, and particularly so to the oral surgeon.

We shall be glad to receive subscriptions for the volumes and forward them to the Secretary, or they may be sent direct to Dr. Henri Villain, Treasurer, 45, rue de la Tour d'Auvergne, Paris, France.

BIBLIOGRAPHICAL

DENTAL ELECTRO-THERAPEUTICS. By ERNEST STURRIDGE, L.D.S., (Eng.), D.D.S., Fellow of the Royal Society of Medicine, Member of the British Dental Association; Member of the British Society for the Study of Orthodontics; Member of the American Dental Society of Europe; Contributor on Dental Electro-Therapeutics in "The Science and Practice of Dental Surgery," and on Ionic Medication in Prinz's "Dental Materia Medica and Therapeutics." Second Edition, thoroughly revised. Illustrated with 164 engravings. Philadelphia & New York: Lea & Febiger. 1918. Price, \$2.75.

This, we believe, is the only work in our literature devoted to the subject of electro-therapeutics exclusively from the dental standpoint, and it is presented by an able and enthusiastic advocate of dental electro-therapeutics and particularly ionic medication in dentistry.

The author devotes the first portion of his work to electro-physics, and while the size of the book prohibits an extensive treatment of this science, the elementary aspect of it is presented in a clear and concise manner, and embodies knowledge which every dentist should have who undertakes to apply electro-therapeutics in the practice of dentistry. A very considerable portion of the work is devoted to the description and management of the various electrical appliances which the dentist is called upon to use.

The chapter on the use of the Roent-

gen Ray in dentistry is quite complete, and contains information that should be in the hands of every dentist who uses the roentgen ray. Under this subject the author proffers some very valuable suggestions in interpreting radiographs, which if closely followed would help to avoid many mistakes that in the past have resulted from "cocksure" diagnoses made from inaccurate readings of the roentgen-ray picture.

The author says in his preface that the book is primarily "intended to bring forward the value of electro-sterilization in treatment of root-canals and periodontal diseases," and this portion of the book has been rewritten and enlarged to cover that subject more specifically than did the first edition, giving in detail the method of procedure and the proper technique to be followed in the treatment of various disease conditions of the apical areas of the teeth, the application of electro-therapeutics as an aid in the treatment of pyorrhea, etc.

ARMY DENTISTRY. (FORSYTH LECTURES FOR THE ARMY DENTAL RESERVE CORPS.) Edited by FREDERICK A. KEYES, D.M.D., former Visiting Dentist, St. Vincent's Orphanage, Boston; Consulting Dentist, Medfield State Hospital, Medfield, Mass.; Librarian and Curator of the Museum, Forsyth Dental Infirmary, Boston. New York and London: D. Appleton & Co. 1918.

The title of this book is "Army Dentistry," and its subject matter consti-

tuted a course of lectures delivered to the "Army Dental Reserve Corps," or, strictly speaking, to a section thereof, at the Forsyth Dental Infirmary. The lectures are presumably an exposition of the curriculum of specialized instruction authorized by the Surgeons-general of the Army and the Navy for officers of the Dental Reserve Corps, as printed in the introductory part of the work. One hundred and sixty-four pages, constituting the first five chapters, are devoted to elementary matters which in more detailed and systematic form are embodied in the standard curriculum of dental schools, and with which the members of the Dental Reserve Corps may safely be assumed to be familiar; therefore, why should they be rehearsed?

The chapter on Maxillary Fractures is open to the same criticism, and further, it is mainly a compilation of methods and appliances taken from older writers of standard works on the subject, *e.g.* Kingsley, Garretson, Heath and Hamilton, and Angle, with a few illustrative cases from the reports of the American Ambulance Hospital in Neuilly by Dr. G. B. Hayes.

Chapters on Examination of the Mouth, Extraction of Teeth, Novocain Technic, Anesthesia, and Roentgenology follow—all of which is old and familiar matter to the dental graduate.

The chapters on Surgical Technic and Bandaging, Infective Diseases, Venereal Diseases, Appearances of the Mouth in Some of the Common Infectious Diseases, Recent Advances in Dental Surgery and Technic, and on Military Administration are interesting and are germane to the scope implied by the title of the work, but we confess that our

inductive reasoning faculty is taxed to a degree in the endeavor to trace out the connection between "Army Dentistry" and the following information with respect to the Care of Horse: "If a horse has been brought up in the army, he has been taught by experience to take care of himself. . . . If a horse is not acting normally, his rider can be sure he needs food or water or some of the other essentials"—in which respect, we may add parenthetically, the horse resembles a flivver, but differs therefrom in the respect that, to quote again, "He must be approached on the right side and never riled."

We cannot conscientiously say that we think this book fills a long-felt want, or at any rate a generally recognized need.

Books Received.

Books received are acknowledged in this column, and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender. Selections will be made for review in the interests of our readers and as space permits.

"Oral Primer." Presented by the Educational Committee of the Genesee County Dental Society, New York.

"Prophylactic Rhymes." Published by the Oral Hygiene Committee of the Dental Society of the State of New York. Copies of this booklet may be procured from Dr. A. W. Smith, 33 Chestnut st., Rochester, N. Y., chairman of the Oral Hygiene Committee.

"A Child's Book of the Teeth." By HARRISON WADSWORTH FERGUSON, D.D.S. Illustrated by the Author. Yonkers-on-Hudson, New York: World Book Co., 1918.

A commendable group of primers intended for the instruction of school children in oral hygiene, presenting methods of caring for the teeth in an interesting and attractive manner which should appeal to the little ones.

REVIEW OF CURRENT DENTAL LITERATURE

[*Journal of the American Medical Association*,
Chicago, May 11, 1918.]

A Surgeon's Impression of Trigeminal Neuralgia, Based on Experiences with 302 Cases. BY CHAS. H. FRAZIER.

True trigeminal neuralgia must not be confused with a peripheral neuritis initiated by some infective focus in tooth or sinus, or with the neuritis of toxic or obscure origin. One occasionally hears or reads of the cure of trigeminal neuralgia by the drainage of a sinus, by an intranasal operation, or by the removal of an infected tooth. Frazier has never seen or operated on a patient in a case of the major type of trigeminal neuralgia in which there was any reason to suspect any one of these lesions as the exciting cause. If this were accepted, it would serve one useful purpose; that is, vain attempts to find peripheral lesions as a cause would be abandoned, and patients would be spared many sinus operations and the extraction of a majority of sound teeth.

The facts presented in this paper are the outcome of an experience with 302 cases of neuralgia of the trigeminal nerve. This includes 39 peripheral operations, 99 alcoholic injections, 130 intracranial operations, and 34 cases that were not treated.

There are no grounds for discussing any method of treatment other than alcoholic injection or the avulsion of the sensory root. The alcoholic injection is of only transitory effect. Properly given, it will arrest pain immediately and absolutely, and for an average period of nine months. It is in no sense of the word a permanent cure. The radical operation assures absolute and permanent relief. As an exception to the generality of these two methods, there are a few cases in which the pain is limited to the distribution of the supra-orbital branch. Alcoholic injection of this branch is not very effective;

peripheral resection may with propriety be employed first.

The untrained physician is no more qualified to employ alcoholic injection than he is to perform the operation. Frazier stresses the fact that with confidence born of experience the injection may be made painless. Great caution must be taken as to the injection of the Gasserian ganglion. The incidence of corneal complications, apart from injuries to the abducens and oculomotor nerves, is not small. The toll is too high, and Frazier makes prohibitive the treatment by injection, except in the few instances in which the operation may be contra-indicated.

Since 1901, in almost all his cases Frazier has practiced the avulsion of the sensory root as a substitute for gangliectomy. Physiologically sound and technically practical, the avulsion or even the division of the sensory root is in every sense a radical cure. Frazier gives the general principles of the technique, and this part of the article is very well and clearly illustrated.

In considering the results Frazier refers only to the major operation. There can be no doubt as to the permanence of relief if the entire root is sectioned. His first operation was performed in 1901, and when last heard of, fifteen years after the operation, the patient was free from pain. In all his 121 intracranial operations, he has only once been called to operate a second time. In this case the inner portion of the root had escaped section. The motor and sensory sequelæ are of no very great moment, at least when compared with the intense suffering for the relief of which the operation is performed. The only sequel that might be said to be of serious moment is keratitis. If promptly recognized and properly treated the corneal ulcer will heal.

There seems to be an extraordinary misconception on the part of the profession as

to the status of the operation on the ganglion or root. It is usually represented as a sort of kill-or-cure method, as a result of which the patient, if he survives, will be paralyzed on one side of the face, and will lose his eyesight. Because of the frame of mind in which the patient consults the surgeon, the former needs some reassuring. In stating the risks of the operation, Frazier refers only to his own clinic. Since 1901 there have been four deaths in 160 operations. Two of these were due to apoplexy, and all of them were among the subjects of the 121 intra-cranial operations. In a series of 87 consecutive operations there have been no deaths since 1912.

Over other radical operations, such as the removal of the ganglion, the Abbe operation, or the Hutchinson operation, avulsion of the sensory root has so many advantages that it should be and is recognized as the operation of choice. It is easier of execution than any other; it subjects adjacent structures to no risk, and it is attended with a smaller percentage of corneal complications and with a lower mortality.

The Bactericidal Action of Arsenical Compounds on Experimentally Produced Streptococcic Septicemia. BY CLARENCE S. ALLISON.

It has been known for some time and now is generally appreciated that in those cases of pyorrhea alveolaris or other gingival affections in which spirochetes could be demonstrated the various organic arsenical preparations exert an almost specific action. In the *British Dental Journal* for March 15, 1918, p. 197, is a note to the effect that W. Kolle has identified a particular spirochetel form which he believes plays the principal part in pyorrhea, and records marked improvement sequent to intravenous injection of neosalvarsan.

The present study of Allison is of interest in that it demonstrates that the indubitable clinical improvement following administration of arsenicals is not of necessity solely attributable to their spirocheticidal specificity.

Colebrook and Douglas (*Lancet*, London, January 22, 1916, pp. 81 and 181) proved

that salvarsan and neosalvarsan are bactericidal for cultures of staphylococci, both in watery solution and in the serum and whole blood of patients who had received therapeutic injections of arsenical compounds. Allison here offers experimental work showing that salvarsan, neosalvarsan, and arsenobenzol have a marked bactericidal action on different strains of streptococci *in vitro*, and that these arsenicals are of value in the treatment of experimental septicemias due to these organisms.

For this work, there were used fifteen different strains of streptococci, representing both the hemolytic and the viridans groups. It is inferable that none of these strains were isolated from dental lesions. The experimental animals were rabbits.

The results of Allison's study with watery solutions of salvarsan, diarsenol, and arsenobenzol lead to the following conclusions:

(1) They possess a distinct bactericidal power against virulent strains of streptococci *in vitro*, in dilutions up to 1:3000, and an inhibiting power over these organisms for at least twenty-four hours in weaker dilutions.

(2) They possess a bactericidal action against streptococci in the blood stream of animals (rabbits). The success of the treatment depends largely upon the virulence of the organisms, and upon reaching them before they become localized in remote parts of the body.

(3) They produced no untoward effects on the animals in which the maximum doses were frequently repeated.

Miller and Chalfant (*Journ. A. M. A.*, June 22, 1918, p. 1975) give a note upon the treatment of puerperal blood-stream infection by means of arsphenamin. In seven of the women a streptococcus was found in the blood. "With the intravenous injections of arsphenamin we have been able to rid the blood stream of its invading organism in every instance. All varieties of organisms so far encountered seem to be equally influenced. After arsphenamin has been given there is a marked increase in the leucocyte count." These clinical results strikingly confirm Allison's laboratory findings, and suggest that the good clinical results of pyorrhea treatment with arsenicals are possibly attributable not solely to their spirocheticidal properties.

Retention Cysts of the Mucosa of the Lip.

By R. L. SUTTON AND F. SIMPSON.

Sutton had several cases of these retention cysts on the lower lip. They were about one-fourth to one-half inch in circumference, covered with normal mucous membrane, and contained mucous secretion and cells. He had treated them by evacuation, cauterizing the base with some chemical agent. W. A. Pusey had had considerable success in treating these cysts by the cautery.

The Lipoids in Tumors of the Dental System. By K. W. DEWEY.

The chief lipid in tumors about the mouth, as in other parts of the body, was cholesterol, occurring as the stable ester compound and much more frequently in more or less loose combinations with fatty acids and other lipoids. Such crystals were mostly doubly refractive. Mixtures of cholesterol with glycerin esters or neutral fat had no such properties. In the tumors studied cholesterol in these various forms was found to occur much more in the connective tissue stroma, in endothelial and other connective tissue cells than in the tumor cells themselves. A noteworthy observation was that frequently leucocytes were completely filled with these lipoids. A finding which is almost without notice in the literature was the presence of fatty acids and soaps in the zone of squamous epithelial cells of papillomata and other pathological conditions of the mucosa. A condition resembling cornification of the epidermis, characterized by the occurrence of fatty acids, was not so rarely found. The lipid substances associated with degenerative processes found in tumors of the dental system were possibly particularly suitable for investigation of the important question as to what substances were involved in the process of calcification.

Use of Heat and Radium in Treatment of Cancer of Jaws and Cheeks. By G. B. NEW.

In the cases treated there was no glandular involvement. The method consisted of the thorough cautery of the growth with slow heat for from twenty to forty-five minutes.

A soldering iron and a water-cooled retractor were the most satisfactory means of cauterization. This was followed by radium treatment. The immediate results of this treatment in this group of cases are very encouraging. Twelve of the twenty patients on whom this report is based had no recurrence locally or in the cervical lymph nodes for from six to eighteen months.

Progress of the Year in the Investigation of Mottled Enamel, with Special Reference to Its Association with Artesian Water. By FREDERICK S. MCKAY.

The present report is primarily a survey of the geographical distribution of this peculiar lesion, with special emphasis on the artesian basin of South Dakota. The evidence presented by the examinations of this district make it plain that there is a relation most definite and conclusive existing between the use of water drawn from these artesian wells during the period of enamel growth and the existence of the enamel lesion.

Another endemic region is found in the Bahama Islands. In this locality it appears that if the water be the cause of the lesion it is because of something it takes from the soil, since water which does not come into contact with the soil (rain-water gathered in tanks) is unassociated with mottled enamel. It is difficult to understand what relation can exist between water obtained from the shallow wells in these limestone coral islands, in the ocean, and that flowing from the Rocky Mountain range, hundreds of miles underground, to supply deep artesian wells far in the interior of the country (South Dakota region). Undoubtedly it strengthens McKay's attitude in directing the study of this problem, that the only way a solution can be reached is by a most careful comparative chemical analysis of the waters.

The rest of the report is occupied by a consideration of two theories which have been advanced to explain the etiology of mottled enamel.

Grevers of Utrecht, Holland, is decidedly of the opinion that thyroid disturbance, or at least underlying constitutional factors, will be found to contain the solution of the difficulty. The one circumstance connected with

glandular dystrophy (goiter and cretinism) that exists in common with mottled enamel is its sharply defined geographical localization. But against the correctness of this analogy is the fact that the individuals with mottled enamel fail in any particular degree to present unmistakable evidence in other parts of the body of malfunctioning of the endocrine organs.

Grever's conclusion is that mottled enamel is simply immature or not fully calcified enamel, and not a manifestation of an inherent lack of the cementing substance. Whether or not this view be eventually corroborated, to McKay the real problem remains unchanged, viz. to locate the influence which either prevents the maturing of the outer layers of the enamel or else partially destroys this layer after it has once been fully formed.

The second theory to be discussed by McKay is that of Gasparini and Piergili (see DENTAL COSMOS, July 1918, p. 631). In harmony with the views of these men, in the American endemic districts the waters have been lacking in "mineral salts in general, and in calcium salts in particular." But the conditions in the Bahama Islands' endemic region invalidate the significance ascribed to the calcium content of the potable waters. These islands are coral reefs, solid, calcareous material. What shall we say of rain-water with reference to its lime content after running over and through such a soil?

It seems to McKay that the conception of Gasparini and Piergili of this lesion and its production is faulty in its first fundamental, and it cannot be understood how they failed to notice that teeth which have mottled enamel erupt with the enamel in this condition, which means that this is brought about during the developmental period, and before the enamel could possibly have come into contact with any water which passed through the mouth during the act of drinking.

In conclusion, McKay states his belief that the damage is wrought by some influence which acts either in an inhibitory or in a destructive way upon the enamel during or immediately after the building period (which of these two hypotheses, if either, will finally be found to be correct, it is impossible at present to say), and reiterates that the con-

dition is established prior to eruption (*contra* Piergili).

Salivary Calculus. BY W. W. CARTER.

[*Revue Médicale de la Suisse Romande*, November and December 1916, per *Laryngoscope*, St. Louis, March 1918.]

Acute Suppurative Whartonitis.

The latter of the two above articles is a brief case history. It concerns a woman, age forty-eight years, complaining of severe pain and swelling in the right submaxillary region, difficulty in opening the mouth, salivation, and immobility of the tongue. Examination revealed a calculus in Wharton's duct, which when extracted was found to be 1.5 cm. long and 2 mm. thick. It had a slight longitudinal groove so that the duct had not been completely occluded. Removal of the calculus was followed by escape of thick pus.

The subject of Carter's report was an adult male, who experienced a sudden, stinging pain on the right side of the tongue. The right side of the floor of the mouth became swollen, increasing rapidly on taking food, and subsiding a short time after a meal. A small calculus, about the size of a mustard seed, could be seen obstructing the mouth of Wharton's duct. Upon removal, symptoms disappeared.

A little less than two years later there was a reappearance of similar symptoms. The X-ray showed a large, pear-shaped calculus and two smaller calculi. On removal the largest was about the size of a cherry pit; the small ones about the size of mustard seeds.

After apparently almost immediate recovery from the operation, there occurred an unexpected complication, which Carter has not found mentioned in the literature. On the third day after operation the opposite submaxillary and both sublinguals became sympathetically involved, and for four or five days the patient was completely incapacitated. The parotids did not participate.

Sixty per cent. of salivary calculi are said to be found in the submaxillary glands, twenty per cent. in the sublinguals, and twenty per cent. in the parotids. The stones are usually found in Wharton's duct, where they are generally round or cylindrical. When found

in the gland they are usually larger, irregular, and multiple.

Carter is inclined to look upon salivary calculi as the result of a local inflammatory process—a clump of bacteria serving as a nidus around which is deposited the salts of the saliva. The prompt removal of calculi, especially if they are located in the gland, should be urged, not only on account of the pain but because of the likelihood of abscess formation, which may result in cellulitis, a condition always to be dreaded in this locality.

[*Medical Clinics of North America* (Philadelphia number), September 1917.]

Ulcerative Endocarditis, Secondary to Dental Sepsis, Treated by Autogenous Vaccine. BY JUDSON DALAND.

The three cases which furnish the text of this clinic are those referred to by Daland in the *DENTAL COSMOS*, 1917, p. 1101.

Case 1 was a man of forty-three, complaining of weakness, mental depression, fear of crowds, tremor, irritability, epigastric distress with distention, attacks of fever at intervals of from ten to fourteen days, loss in weight of thirty pounds. These symptoms began six months ago. Family and personal history were unimportant. The maxillary left premolar and first molar and right molar were crowned. Absence of teeth on the right side prevented good mastication. By exclusion of other possibilities resort was had to radiographing the teeth. This showed periapical abscesses at the roots of the left mandibular premolar and first molar, and left maxillary second premolar. Exploration showed that the left maxillary second premolar contained cotton, offensive in odor. The root-canal was enlarged, and cultures taken, yielding a non-hemolytic streptococcus of low virulence. From this a vaccine was made. The infected teeth were extracted and the sockets curetted. The equivalent of 500,000,000 organisms was injected at intervals of five days, later increased to 750,000,000, and toward the end gradually decreased to 150,000,000. The leucocytes were increased 1000 after the first injection; the larger doses caused depression. Vaccine treatment was continued for two months and was of no benefit. Death ensued. In Daland's opinion the beginning of this fatal illness was due to

septic ulcerative endocarditis involving the previously diseased mitral valves, secondary to streptococcus infection from tonsils or roots of teeth, or both. The large doses of vaccine did harm by causing increased weakness.

Case 2, male, age forty-one. During the past three or four years the patient had had abscesses about the apex of the right maxillary first premolar; he complained of feeling tired, aching pains in legs, night sweats, fever, loss of weight, anorexia, increased pulse rate. Vaccine prepared from an hemolytic streptococcus isolated from the blood stream gave no observable benefit. The disease steadily progressed, culminating in death. The history, examination, and autopsy all combine to show that this was a typical case of septic ulcerative endocarditis, involving the mitral and aortic leaflets, and it is probable that these diseased valves became infected with the hemolytic streptococcus from the roots of certain teeth.

Case 3, male, age forty-six, complained of weakness, chills, fever, sweats. The family history was negative. Radiographs showed abscess on the distal root of the right maxillary second molar. This tooth was removed. Considerable pus escaped. Fever, leucocytosis, and polyarthritides disappeared, and there was general symptomatic improvement, but death took place twelve days later. The marked though temporary improvement following the extraction of the infected tooth suggests that greater benefit might have been secured if that focus had been removed earlier; on the other hand the periapical abscess may itself have been secondary, as the tooth showed no evidence of previous disease.

[*American Journal of Physiology*, Baltimore, March 1, 1918.]

Orokinase and Ptyalin in the Saliva of the Horse. BY C. E. HAYDEN.

It has been claimed that there exists an enzyme, present in the buccal and possibly the lingual glands, that activates in ptyalinogen present in the secretion of the salivary glands of the horse. From this point of view neither saliva obtained from a parotid fistula nor a glycerin extract of the parotid gland digests starch. The same claimants assert that the mixed mouth secretions obtained from an esophageal fistula are more powerful

in their amylolytic action than those obtained from the mouth. The name orokinasé is given to the activating enzyme which activates the parotid saliva, and the claim is made that the enzyme is present in the mouth secretions of both horse and man.

In Hayden's present work, parotid saliva from the horse was collected through a fistula from the horse's duct. Mixed saliva was collected from both the mouth and an esophageal fistula. Mixed human saliva was obtained from a large number of persons. Parowax was chewed in each case to stimulate the flow. Various extracts were made with fifty per cent. glycerin in water.

The data and the inferences therefrom afforded by this study have been summarized by the author as follows:

(1) Pilocarpin hydrochlorid does not digest starch. Hypodermic tablets of both pilocarpin and arecolin contain a reducing substance in comparatively large quantities, but do not in themselves digest starch.

(2) Two drops of human saliva diluted 1:50 carry 5 cc. of a one per cent. starch solution to the erythrodestrin stage in a large number of cases. A measurable amount of sugar is produced as a result of that digestion.

(3) Human saliva in such a dilution does not activate either mixed or parotid fistula saliva from the horse.

(4) Mixed human saliva digests cooked starch much more readily than either mixed or parotid fistula saliva of the horse.

(5) Two drops of mixed mouth saliva from the horse diluted 1:10 does not activate parotid fistula saliva from that animal. It does not show any appreciable digestive power when used alone in that dilution.

(6) The filtrate from a solution of ground corn or oats contains a reducing sugar. The quantity of sugar does not show an average increase when the grains are digested with either mixed or parotid fistula saliva from the horse. Mixed human saliva does digest them under the same conditions.

(7) Extracts from the glands and mucosa of the mouth have failed to activate parotid saliva or extracts of the salivary glands of four different horses.

(8) Corn and oats passed through an esophageal fistula show no more reducing sugar than the ground grains themselves. Mixed

saliva from the esophagus has not shown any marked potency.

(9) The glands of the mouth as well as the salivary glands produced a small amount of enzyme that will digest starch within a twenty-four-hour period.

[*Pennsylvania Medical Journal*, Athens, January 1918.]

Diseases of the Eye from Focal Infection. BY ADOLPH KREBS.

[*American Journal of Ophthalmology*, Chicago, May 1918.]

Blepharospasm Secondary to Pyorrhea Alveolaris. BY H. M. THOMPSON.

Krebs presents essentially seven case histories, which in a condensed form follow:

(1) Asthenopia, a woman of forty-eight years, under observation eight years. Radiographs showed periapical abscesses on both right and left maxillary first molars. These teeth were extracted. Marked improvement took place within two months, and at the present time (two years later) she can read or sew for hours without fatigue or discomfort.

(2) Asthenopia, man of thirty-seven, under observation four years. No correction was comfortable more than a few months at a time. An extensive periodontal abscess in the right maxilla was treated and cured. All ocular symptoms disappeared.

(3) Asthenopia with marginal blepharitis, woman of twenty-one, under observation three years: was cured within a month after extraction of two abscessed left maxillary molars.

(4) Episcleritis, woman of thirty-eight, under observation seven years. No treatment had any permanent effect until two teeth were extracted. This gave complete relief for one year: then a return of the episcleritis occurred. Removal of an infected tonsil was followed by a clearing up of the inflammation. No sign of recurrence was noted for at least two years following.

(5) Phlyctenular keratitis, girl of eleven, under constant treatment for sixteen months. Extraction of an infected right mandibular first molar resulted in the prompt disappearance of the hitherto incurable photophobia and the cessation of the phlyctenular process. There was no return for at least a year.

(6) Iridocyclitis, woman of fifty-five, under

observation three years. During the second year of unsuccessful treatment there was extracted an infected molar bridge abutment. Progressive improvement has since taken place.

(7) Uveitis, woman of thirty, under observation seven years. The radiograph showed an impacted and infected right maxillary third molar, also a left maxillary molar with a periapical abscess extending into the antrum. These were removed, and in two weeks there was marked improvement. During the next two months she had an attack of dimness lasting ten minutes. Her left antrum was operated upon, since which time there has been no return of the attacks.

Thompson's article is a brief case history which is in line with those just recorded. The patient was a man of fifty-two, in excellent health except for "rheumatic attacks." He first noticed a conjunctival irritation. A few days later the lids closed tightly in a tonic cramp. General examination; urine and Wassermann negative. For four weeks varied remedies were tried in vain. A rather severe pyorrhea suggested the chance of focal infection. The teeth were all removed. On the next day the patient was able to open his eyes, and on the fourth day was apparently in normal condition.

Thompson interprets the long-continued cramp of the orbicularis muscle as secondary to a toxic inflammation of all the coats of the eye, due to focal infection.

[*Annals of Surgery*, Philadelphia, May 1918.]

Loose Cartilage in the Temporo-Maxillary Joint. BY RICHARD J. BEHAN.

The patient was a female, of apparently adult estate, whose chief complaint was inability to close her mouth so that the teeth would come together. It seemed that the entire mandible was swung toward the right side, so that the line of the teeth of the lower jaw was at least one-half inch from the line of the upper teeth. The lesion had been present for eight months, having resulted from a difficult effort at mastication. At first the jaw locked, but by persistent effort she was able to release it. This happened several times, until the locking in the position above described became permanent and could not be released.

A study of the joint convinced Behan that

the locking was due to a separation of the left interarticular cartilage, with a forcing back into the temporo-maxillary articulating cavity.

No description of an operation for the correction of this deformity could be found, so the author devised a technique which is given in detail. The patient made an uneventful recovery, leaving the hospital in eight days. The teeth were in perfect alignment, mastication was normal. After a lapse of eighteen months, the left joint gave no trouble, although there was some crackling in the right joint.

[*American Journal of Physiology*, Baltimore, April 1, 1918.]

The Salivary Factor in Relation to Dental Caries. BY PERCY R. HOWE AND MILDRED R. KENISTON.

The authors report their work upon the relation (if any) between the salivary factor and the incidence of dental caries. The "salivary factor" is an arbitrary and empirical standard to represent the degree of the saliva's power to maintain a neutrality in the mouth.

Marshall's procedure was followed. All subjects were of about the same age, ten to fifteen years. From an abundance of clinical material it was easy to eliminate any doubtful intermediates, and to choose only the two extremes, those children showing absolute immunity to dental caries and those showing excessive decay.

From the observations made on these cases, it would appear that the saliva of persons with teeth immune to caries varies, as does also the saliva of persons with carious teeth; that saliva may neutralize substances taken into the mouth, and that the average immune mouth has the greater power of neutralization; but the ratio of resting and activated saliva in immune mouths does not vary enough from that of carious mouths to prove that this ratio is indicative of the production and maintenance of immunity to caries in any individual. The tables compiled do not show consistently that as the difference between the total neutralizing powers of the resting and activated saliva diminishes, liability to incidence of caries increases. Since the average ratio or salivary factor is below 80 in both immune and carious mouths, there

is doubt as to the importance of this mark in the relation of the salivary factor and dental caries. Furthermore, no constant points of difference can be found to correspond with the differences in salivary factors, and in Howe's and Keniston's work no substantial proof can be found to verify a relationship of the salivary factor to dental caries. This conclusion is in harmony with and confirms the findings of Gies and his collaborators.

[*Journal of Cutaneous Diseases*, Chicago, October 1917.]

Focal Infection in the Etiology of Skin Disease. By E. D. CHIPMAN.

The aim of this paper is to report the observations in fifty consecutive cases belonging to those dermatoses which may be suspected of having a focal origin. For the most part it records only the incidence of focal infection in these cases. Chipman does not present this study as a protagonist. For him it is simply a preliminary survey of the field, which may later be found to be fertile or barren. The statistical method which he employs is justifiable for this purpose, and its results may be suggestive, but are never to be considered conclusive of a causal relationship between dental foci and cutaneous lesions.

A summary of this study shows that of six cases of alopecia areata five showed dental infection (long before the days of the doctrine of focal infection there was in the French dental literature abundant reference to the rôle of dental disease in the production of alopecia areata, and the earlier pages of the DENTAL COSMOS contain numerous notes on this subject); of two cases of chilblains each showed dental infection: of four cases of circumscribed eczema each showed dental infection; of two cases of erythema multiforme one showed dental infection; the one case of granuloma annulare encountered in this study showed dental infection; of two cases of herpes progenitalis one showed infection of the maxillary sinus: of two cases of herpes facialis each showed infection of the teeth; of four cases of lichen planus each showed dental infection: of two cases of lichen simplex of Vidal each showed dental infection: of seven cases of psoriasis five showed infection of the teeth, and one infection of both

teeth and tonsils; the single case of Raynaud's disease showed infection of teeth and tonsils; each of seven cases of rosacea showed dental infection; likewise for the two cases of urticaria, the three cases of vitiligo, and the two cases of zoster.

Out of the fifty cases, thirty-five showed infection of the teeth alone; four showed infection of both teeth and tonsils; one of teeth and appendix, and one of accessory nasal sinus (maxillary).

One circumstance observed in several cases of this series merits special remark, namely, the tendency to the development of symptoms on interference with an active focus. For example, in one case of rosacea a marked exacerbation followed active treatment of an apical abscess. This, however, soon subsided, and was followed by a corresponding improvement. In one of the cases of neuritic eczema in which two apical abscesses were treated, a slight exacerbation followed the interference with the teeth. This was followed by a month in which no progress was made, at the end of which interval the condition spontaneously resolved.

Another point worthy of emphasis is that it is not necessary to find the same micro-organism in the skin lesion that is found in the original focus in order to suspect the latter of being in etiologic relationship with the former.

The above paragraph, together with the central thought (anaphylaxis) of the following quotation from Chipman's article—"If we accept it as established that anaphylaxis results from focal infection we must consider it possible that the dermatoses caused by hypersensitiveness are ultimately due to focal infection"—is found in a developed form in Duke's "Oral Sepsis" (*vide* DENTAL COSMOS, July 1918, book review).

In the discussion which followed this paper, Sutton reported that in seventy-five of a series of one hundred cases of skin diseases specifically studied, there was marked improvement or complete cure after removing the focus of infection. *e.g.* a case of lichen planus labialis was cured, sequent to the removal of several apical foci. Another case was that of a chronic eczema which failed to respond to any treatment until the mouth had been put in a healthy condition. Sutton and his colleagues, in cases where simple re-

moval of focus failed in results, resorted to autogenous vaccines.

R. A. Davis reported an obstinate case of dermatitis herpetiformis. The patient was treated with emetin for pyorrhea alveolaris, and the skin lesion healed immediately. Since then he has had the same experience with six or eight similar cases.

Engman spoke of a case of superficial gangrene of the fingers and gangrenous spots on the penis with Raynaud's phenomena of both hands and feet. The patient disappeared. Nine years later he returned with toenails extracted and finger-nails scarred, still having some trouble. For twelve years he had had a constant virulent intermittent oral infection. This was cleaned up. Immediately all of his objective and subjective symptoms disappeared.

Morrow mentioned a case of eczema of face and neck of many years' duration. Radiographs showed many apical abscesses. A few hours after the extraction of the teeth the man felt much better. A few days later the rash had almost disappeared. In the course of a few weeks the eruption entirely vanished.

Heinmann reported a case of a man age sixty, with typical pityriasis rubra of the Hebra type. His teeth were in a very bad condition. These were extracted, and within two weeks the man was well and had been well since (three years from the time of the extraction).

Hartzell of Philadelphia spoke of a man with a severe pustular eruption on the palms of both hands and other symptoms. The antrum was found to be infected. After thorough drainage his symptoms began to subside. Slowly but certainly they disappeared.

[*Medicine and Surgery*, St. Louis, February 1918.]

Fibroma of the Tongue, with Consideration of Other Tumors of the Tongue and Certain Technical Points in Tongue Resections. BY JOHN W. CHURCHMAN.

Although a lingual growth usually is identified as a fibroma or a cyst, a tuberculous or a syphilitic granuloma, or a carcinoma, Churchman presents a list of twenty-two types of newgrowths of the tongue which have been reported in the last twenty years.

A fibroma is in a way a rarity. It may resemble a cyst, but the chief difficulty which it presents is that of excluding sarcoma. Often this requires the utmost care, even in the study of microscopic sections.

Churchman's case here reported concerns a man, forty-four years of age. The growth was first noticed two months before admission to the hospital. There were no unpleasant symptoms. The growth was removed by a wedge-shaped incision, done between stay sutures. Convalescence was uneventful; the tongue functions perfectly.

As regards the technique of operations on the tongue, experience has taught the author—(1) Never to touch the inside of the mouth with a knife. The entire resection of the tongue and floor of the mouth is done with a cautery. This, combined with the stay sutures, eliminates hemorrhage. And (2) Where malignance is suspected, to remove the tongue by the jaw-splitting operation, preferably two to three weeks after a complete and very radical dissection of the glands on both sides of the neck, and after these wounds have been allowed to heal.

[*Surgery, Gynecology, and Obstetrics*, Chicago, July 1918.]

Mixed Tumors of the Salivary Glands: A Study Based on the Experimental Production of Neoplasm in the Submaxillary Gland of the Dog. BY ALEXANDER FRASER.

This is a broad and judicious consideration of the subject. There are a number of valuable illustrations, which are well reproduced.

Fraser describes briefly the principal theories of the origin of these growths, and then proceeds to report an experimental study of the morphological reaction of the salivary glands to injury, which was undertaken with the object of observing the regenerative changes on the part of the salivary epithelium, and whether the character of such changes would serve to establish any definite clue as to the origin of the mixed tumors.

Frazer summarizes and discusses this work as follows:

(1) The mixed tumors arise from the ducts of adult glands. No claim is made that true neoplasm has been experimentally produced, but the experimental results justify the con-

clusion that the primary structures of the mixed tumors may easily arise from the ducts of the adult gland.

(2) The endothelial theory has no foundation in fact. All the so-called endothelial structures are easily explained as natural modifications of primary duct formations.

(3) Injury, such as localized or partial obstruction of ducts, probably plays a prominent part in the origin of these tumors.

(4) The cartilage is developed from the epithelium of the parenchyma of the tumor. This claim will undoubtedly meet with strong opposition.

PERISCOPE

Chinosol in Root-filling.—Root-canal fillings that are to be radiographed will have a denser outline if chinosol is incorporated with chloro-percha, and pumped into the canal before inserting the point. Chinosol being a good antiseptic is particularly indicated in canals that have been putrescent.—VICTOR H. FRUQUA, *Dental Review*.

Method of Polishing Vulcanite or Metal Plates.—After filing and scraping, use a leather washer (the same as is used for the ordinary water tap) on the lathe in conjunction with equal parts pumice and emery powder (knife polish). This quickly takes out all scratches without the use of sandpaper. Proceed then with the brushes in the usual manner.—*Oral Health*.

To Obtain Smooth Finish on Palatal Surface of Vulcanite Dentures.—After the case has been invested, separated, and the wax boiled out, paint the cast with liquid silic. Allow to dry thoroughly before closing the flask. This eliminates the burnishing of tin foil, which tends to wrinkle and tear during the process, resulting in a rough and unsightly finish to that part of the denture.—LESTER N. ROUBERT, *Dental Review*.

Pulpless Teeth.—The writer does not agree with the oral surgeon who radically condemns every pulpless tooth; on the contrary, he knows it is possible, if the patient will present in time, to remove the pulp and aseptically fill vital root-apices, in a large percentage of such teeth, with no post-operative periapical infection, a fact which can be established radiographically and by cultural tests; but he does not believe that an infected or abscessed root apex should be retained for a minute, nor would he spend that time on one, unless attempting apicectomy.—CLARENCE J. GRIEVES, *Journ. N. D. A.*

Removing Silver Nitrate Stains.—Many times, even though one may be very careful, a little silver nitrate will fall on the hands of an operator and cause a great deal of discoloration and also discomfort in operating. When this happens, soak the hands for about fifteen minutes in water as hot as one can stand, and then very carefully rub the spots with pumice stone. The spots will be seen to disappear without any injury to the part treated. After the black color caused by the dead skin entirely disappears, soak the hands in almond cream. Very large spots may require a few treatments at short intervals before the black color entirely disappears.—W. E. WHITTAKER, *Dental Review*.

Root Surgery.—To skilfully perform root surgery requires a perfect technique, plenty of time, and the utmost delicacy of touch in the use of the instrument, so that one may know by the feel of the blade just when the infected peridental membrane and outer layer of cementum has been removed. Our fingers must be our eyes, as we are working in the dark, but even so, there is no more need of mutilating a tooth with a plane than there is of mutilating it with a bur or any other instrument, and only the careless operator will do so. With this instrument the healing is accomplished by hyperemia, induced by the trauma of the operation, and no medicine is used.—EDWARD A. ROYCE, *Dental Review*.

To Hold a Fractured Jaw for Impression and Adjustment.—In all articles on fracture of the jaw, there seems not to have been given the most accurate way of taking a successful impression. Make rather loose-fitting bands of regulating strip of about 36 gage or Liberty (*née* German) silver 38 to 40 gage to cover two teeth on each side of the fracture, solder each pair firmly together,

and then accurately align the edges of the teeth at the fracture with the bands slipped on; then hold the two sections of bands in line with sticky-wax, remove, solder them together, and cement into place for a permanent splint. This will allow you to take an impression or do any other work necessary, without pain to the patient, and with greater assurance of success than by sawing the model and trying to adjust fragments.—*Dental Summary.*

The Interproximal Contact Point.—The form of the contact point has much to do with comfortable mastication and the preservation of normal gum in the interproximal space. The contact point on normal human teeth is a small curved eminence on the proximal surface near the occlusal or incisal. From this small contact the proximal surface of enamel slopes away more or less abruptly, leaving the area in actual contact exceedingly small. This holds true of broad teeth like the molars as well as of narrow teeth like the incisors or cuspids. The philosophy of this narrow contact relates to the fact that when food is forced between the proximal surfaces of the teeth, as it will be at times, it is not retained there owing to the limited area. If the contact were broad, as we sometimes see it on fillings, food particles would be held between the teeth, leading to all the evils associated with this condition.—C. N. JOHNSON, *Dental Review.*

Cancer of the Mouth and Face.—Medical research has established the fact that cancer is a local disease at its beginning, and that every case might be cured if treatment (operation) were performed early enough. And what is true of cancer in general is especially true of cancer of the mouth and face. Bloodgood has shown by his experience that an early diagnosis and prompt radical treatment will cure eighty per cent. of such cases, and states that this number may be increased to one hundred per cent., if the diagnosis is made sufficiently early. As has been stated by Means and Foreman: "The operative technique of tumors of this region has reached a high state of perfection, and if further advance is to be made against cancer of the buccal cavity, it must be by the earlier recognition of the disease." There is, then, a grave responsibility placed upon the person first seeing these cases, and this person in the natural course of events is frequently the dentist.—ERNEST SCOTT, *Dental Summary.*

Extracting Diseased Teeth.—It is the common practice among many to extract diseased roots, and leave the wound socket to nature to take care of. In the writer's experience this practice is not only non-surgical, but really of harmful result. When the pulp of a tooth-root becomes diseased, and is not treated properly, the bacterial toxins pass upward into the periapical space, and cause dissolution of those subdental tissues. The radiograph discloses in such cases marked radiopacity, representing cystic degeneration and carious destruction of the alveolar tissues. Obviously the removal of the diseased root or roots cannot remove this tissue. The apical granuloma and the subapical alveolar structure must be removed by surgical curetment, and the socket packed for some time in a series of post-operative visits. By this means alone can the oral surgeon hope to remove whatever vestiges of infected tissue may be remaining to pour their insidious toxins into the blood stream and into the lymphatics to attack the weakened and non-resisting tissues elsewhere in the economy, be they lymph nodes or glands, intestinal lining, or myocardium.—MILLEL H. FELDMAN, *Dental Summary.*

A New Method for Making a Porcelain Crown.—The following described new method for making a porcelain crown will be found to be very practical for bicuspid and molar roots, and especially adapted for short-bite cases when a gold crown would not be desirable. Make a coping with one or two posts, according to the requirements of the case. Then, having the coping placed on the root, take an impression and a bite. Make models and adjust them in an articulator, then remove the coping from the model, and solder a strip of gold plate around the coping on three sides, namely, mesio-proximal, lingual, and disto-proximal, having the gold strip wide enough to reach to, or nearly to, the occlusal surface of the crown as it will be when finished. Then, having selected a facing of the proper shade and size, solder the pins of the facing to the post of the coping. Then make a mix of synthetic porcelain of a shade to match the facing and fill it in upon the coping, which, having three side walls of gold and the facing as a buccal wall, sustains the synthetic porcelain at every point. While the synthetic porcelain is soft carve it to an approximal occlusion with the antagonizing tooth in the articulator, and when fully hardened grind and polish the porcelain to a proper occlusion.—H. A. CROSS, *Dental Review.*

School Clinic at North Tonawanda, N. Y.—At the Payne Avenue school in North Tonawanda a free dental clinic has been opened in connection with the free dispensary which has been maintained at this school for a long time for the examination of school children and for operations on the nose and throat. The free dental clinic has been made possible by the donation of funds from some of the philanthropic people of North Tonawanda, and the Council has promised the Health department that if the clinic proves successful they will put a sufficient sum in the budget next year to continue it in operation. The dispensary has a capacity for four patients (beds), and many operations are done on the nose and throat, removing tonsils, adenoids, etc. The little patients are kept at the dispensary for one day and then taken to their homes. Mr. R. A. Searing, superintendent of education, has been largely instrumental in bringing about this much-needed institution.—*Health News*.

Taking a Bite for Crown or Bridge Work.—One of the most difficult items to contend with in operative dentistry is the taking of a satisfactory bite, particularly where the occlusions are close. When the wax or compound bite is removed it often breaks in two pieces, making it difficult to obtain a perfect cast for the occluding surfaces to be articulated to the crown or bridge about to be constructed, or it breaks when placed on the plaster model. Many ideas have been advanced for overcoming this, such as placing a piece of linen, cut about the length and width of the bite to be taken, then placing the wax above and below the piece of linen, taking the bite in the usual manner. The linen holds the bite together and prevents biting clear through. A better and more rapid way of obtaining this result is the use of the Artieu-bite, a little instrument in which all manner of hard, close, difficult articulations and bites can be obtained in two minutes' time without the possibility of a mistake.—W. E. BEACHLEY, *Dental Review*.

Dietetics and Oral Hygiene.—Associated with an appreciation of the true functions of the saliva and mucus there goes the important dietetic principle or precept that the physiologically correct type of meal is of such a nature or so arranged that it will leave the mouth physiologically clean. I have never as yet come across any physiologist or medical man who has dared to say that the meal should be of such a nature or so arranged

that the mouth and teeth will be left dirty. Yet their precepts and practices would rather indicate that they have a preference for such types of meals. It may be contended in the future that the types of food which we dentists indicate as leaving the mouth and teeth clean or otherwise are not correct in all details—possibly they may not be. Nevertheless we have established a most important principle which was overlooked in the past, and is not at present taught by physiologists. There was something pardonable for dentists in their old injunction to brush the teeth after every meal, for they knew that when the dictates of dietetic specialists were carried out, the mouth, as a very general rule, did require some artificial form of cleaning. It is relatively unpardonable for physiologists not to recognize or to have recognized that the mouth is naturally kept physiologically clean, and should not, under a proper dietetic régime, require the teeth of man to be brushed to keep them healthy.—J. SIM WALLACE, *Dental Record*.

The Clasp as an Anchorage for Partial Dentures.—We have been using clasps ever since practically the advent of dentistry. It is one of the oldest types of means of retaining partial artificial dentures, and strange to say, today it is the most abused plan of supplying partial artificial dentures. It is one of the most universal means of anchoring partial dentures, and for that reason it should be better understood than any other system of anchoring partial dentures, but strange to say, as I have said, the least understood and the most abused system. If you have taken the pains to study these conditions, as possibly I have done more than some of you, if you will only go into the laboratories in the cities and study the impressions that come to these laboratories from the profession generally, with the request to make a partial artificial denture, you will be surprised. Beeswax impressions, beeswax combinations of bites are taken and sent to the laboratories with the request for a partial removable denture of some kind. Is it any wonder that we are receiving the bitterest condemnation of this work? Is it any wonder these appliances are the means of destruction of the natural teeth and their surrounding tissues? The wonder is that they do not cause more destruction than they do. The clasp, to my mind, is an attachment that can be used and should be used in the great majority of cases. As I have already said, there are many instances where these complicated pieces of work are possible, or no doubt indicated, and

may be used to great advantage; but the great mass of these cases, gentlemen, are cases that do not call for this class of work, and we had better spend our time and put forth our efforts in the mastery of the simple forms of clasps that we can use in anchoring these appliances.—F. E. ROACH, *Journ. N. D. A.*

Prosthesis for Oral Mutilations.—In studying the illustrations of cases treated by dentists in the great war we have noticed the very complex appliances that have been used in many cases, and the suggestion has come to us that a simplification of the technical forms would be desirable if the requirements could be met. Many of the dentists who are taking up this war work are inexperienced as technical prosthetists because of lack of experience, and besides they have had little occasion to study the phenomena involved, so that they could not have any very well-defined ideas of the principles involved in designing and constructing suitable appliances for these entirely new conditions. The fundamental objectives to be kept in view are the restoration of the functions of mastication and speech, and so far as may be practicable, of normal facial contour.

Probably the most difficult technical problem will be to secure stability of the appliances that shall make functions practicable. In some cases the tissues are badly mutilated, and in many cases scar tissue from healing wounds has not only changed the usual form of the oral structures, but has produced conditions which make it difficult to adapt any of the usual forms of prosthetic dentures. Many or all of the teeth and large sections of the jaw-bones are often missing from gunshot wounds or because of the surgeon's operations, and the remaining tissues are of such character and condition that little form or surface remains to which definite anchorage may be attached. What is still more troublesome is the fact that the muscles of mastication are destroyed by the wounds or by paralysis, so that the harmony of masticating function is badly deranged. The physics and mechanics as well as the functional requirements should be worked out together, as no real success can be predicted without harmonious control of all the forces involved. It may be that it will be time enough to meet this problem when our wounded soldiers return, but in the meantime it would seem that it would be wise to begin some serious study of this problem, that we may save our men from the inconvenience of

lack of function, or the embarrassment of personal disfigurement.—*Dental Register.*

Maintaining Dryness of Gingival Cavities Without Rubber Dam Especially Useful with Silicious Cements.—The cavity having been prepared with retentive form, apply deliquesced chlorid of zinc, full strength, under the border of the gum margin all around the decayed tooth, also under the gum margin of the adjoining tooth on each side. A suitable cotton-wound broach is best for the purpose. It must be done carefully, so as to produce no hemorrhage. Lip or cheek must be held away to prevent contact with chlorid. It is best to keep the saliva ejector in the mouth from the beginning. After the application is made, the surfaces touched with the chlorid must be at once sprayed, preferably with tepid water, to wash off the chlorid. The momentary contact with the tissues suffices to produce the required astringent effect. Special care is necessary that no chlorid remains in or around the cavity, as it would contaminate a silicious filling. A cotton roll is now inserted and alcohol is applied to cavity, teeth, and gums, and all dried with cotton and blasts of warmed air. It will be found that cavity and surrounding tissues are dry and there is no oozing from gum margins. This dryness can be maintained fifteen or more minutes, changing the cotton roll if necessary. If the filling is to be silicious, all materials and instruments should be within reach before applying the chlorid. After drying as above, the necessary powders and liquid are placed on the slab, mixed, and the cavity filled. Coat filling with cocoa butter and allow time for hardening before removing the cotton roll and saliva ejector. It is best to finish the filling a day or more after insertion. If sufficient excess of cement has been used, cocoa butter is adequate protection, as there is not penetration of moisture through the excess sufficient to affect the finished filling. The brief application of chlorid produces no injury. Should any of it get where it is not wanted, apply plenty of water, which will destroy its caustic effect. Should a slight hemorrhage be produced in working on the cavity, the application of the chlorid as directed will generally stop it, so as not to delay the operation. This method is practical with all gingival cavities, except those on the lingual surfaces of the lower bicuspid and molars. Therefore it is also useful in insertion of amalgam fillings.—VINCENT FISCHER, *Dental Review.*

OBITUARY

Leon VanderWhite—W. Reinoehl.

I WOULD like to invite the attention of the dental profession to the first martyrs to the cause of liberty in the United States Navy during the war with Germany. The inclosed postal card was given to me by my friend and assistant, Leon VanderWhite, pharmacist's mate, 2nd class, just before he embarked upon the U. S. S. Cyclops for the United States. As you will remember, the Cyclops has gone to the port of missing ships, and as nothing

W. R.

L. V. W.

has been heard of her for about four months it is but fair to assume that she went down with all on board.

The other picture is of his chum and classmate, W. Reinoehl, pharmacist's mate, 2nd class, who accompanied him home on the same vessel. These gallant boys at the outbreak of hostilities with Germany promptly enlisted in the U. S. Naval Reserve Force, and were assigned to duty aboard a large vessel of the navy. At the time of enlistment they were freshman dental students in the San Francisco College of Physicians and Surgeons, and their class enlisted almost to a man.

After a period of training aboard the vessel I was on, VanderWhite was assigned to duty

with me in the dental office, and was rapidly promoted through the grades of hospital apprentice, to hospital apprentice 1st class, then to pharmacist's mate, 3rd class, and finally to 2nd class, and had just been recommended for first-class rating. Personally, there was no more likable man on the ship, and he was as reliable and faithful in the performance of duty as was humanly possible. Several times he has told me that he had worked until one or two o'clock in the morning to get the office ready for inspection. This was purely voluntary, and shows the zeal with which he performed this and other duties devolving upon him.

No man can give more than his life for his country. He gave his, willingly volunteering when he knew that at any time he might need to make the great sacrifice. Let the dental profession pause a moment and ponder the bravery of these lads, who died that their country might live.

W. Reinoehl, pharmacist's mate, 2nd class, was likewise a fine young man, who did his duty in every respect, and was equally faithful in the performance of duty, but he was not directly associated with me, and I only knew him as a friend of VanderWhite's, and by his excellent reputation.

I am, sir, your obedient servant,

J. D. HALLECK,

July 1918.

Dental Surgeon U. S. Navy.

Dr. Ammon Osgood.

DIED, August 10, 1917, at his home in Bath, N. Y., from kidney affection, in his eighty-fifth year, Dr. AMMON OSGOOD.

Dr. Osgood was born at Wells, Bradford county, Pa., September 17, 1832, the son of George M. and Mary (Osborne) Osgood. His early education was obtained in the district school of Wells, and at the age of twenty-four he took up the study of dentistry under

the preceptorship of Dr. Louis Eaton of Elmira, N. Y., with whom he remained until 1863. In 1863 he removed to Bath, N. Y., and established himself in the practice of his

in general. Dr. Osgood was what might be called a first-class all-round country dentist of the old school. Soon after establishing himself in Bath, Dr. Osgood's health became

DR. AMMON OSGOOD.

profession, which he continued up to the time of his death.

Dr. Osgood was a mild-mannered, gentle, lovable man, content with living a simple life. He was generous to a fault, faithful in all his dealings with his fellow men, and highly respected by his patients and his townsmen

impaired, and he was compelled to give up his active practice for two years, which time he spent in outdoor work. With partly restored health he again took up practice, but was never able to follow a strenuous life, for the reason that his health was always below normal, and he was compelled to conserve it.

He was, however, so successful in this respect that he was enabled to practice his profession for sixty years.

Dr. Osgood was a member of the National Dental Association, the Dental Society of the State of New York, and the Seventh District Dental Society of the State of New York, serving the last-mentioned society as presi-

dent for the second time at the time of his death.

He was married on December 6, 1865, to Miss Emma Wintermute of Hammondsport, N. Y., who with his brother, Edmund O. Osgood, survives him. Dr. Osgood's remains were buried in the city cemetery of Bath, N. Y., on August 13th.

DENTAL COLLEGE COMMENCEMENTS

Dalhousie University.

THE convocation of the Faculty of Dentistry, Dalhousie University, was held in Halifax, N. S., May 30, 1918.

The degree of Doctor of Dental Surgery was conferred on the following graduates:

John H. Adamson

Lindsay M. Finnigan

Guy N. Stultz

Tulane University, School of Dentistry.

At the commencement exercises of the School of Dentistry of Tulane University, held in New Orleans, La., the degree of Doctor of Dental Surgery was conferred on the following graduates:

James W. Andrews
Joseph F. Bertucci
Thomas G. Biggs
Joseph T. DeBella
Earl G. Eastin

Haim Gittelman
Marion F. Jarrell
John B. Lescale
Robert S. McKeithen

Henry L. Magee
Marian S. Mayer
Theophile M. O'Ferrall
Henry L. Robinson

John B. Robinson
Aldes Rozas
Wilbur D. Trelue
Oscar A. Wolfe

University of California, College of Dentistry.

At the annual commencement exercises of the College of Dentistry of the University of California, held in San Francisco, Calif., on May 15, 1918, the degree of Doctor of Dental Surgery was conferred on the following graduates:

Cedric C. Baronidis
Elmer H. Berryman
Chester G. Butler
Ward G. Cadwallader
Clyde C. Carmean
Chas. W. Craig
James S. Craig
Leon G. Cuenin
Paul Ehorn
Francis W. Epley
John H. Frank

Harry E. Frisbie
Reuben A. George
George A. Goff
Murray H. Groves
Frederick H. Hare
William H. Haskins
Louis R. Hinek
Chester W. Johnson
Otto R. Jungermann
Ernest R. Ker
Carl E. King

Tokutaro Kogure
Matthew Lifschiz
Philip T. Lynch
Leon W. Marshall
Earl H. Mathis
Theodore H. Pohlman
Carl P. Rapp
Leslie H. Reardan
Harris E. Ridenour
Sam J. Roberts

John F. Robertson
Carlton W. Shepherd
Arthur C. Stabler
Emil Stern
Thomas E. Tilden
Chalmers E. West
Sylvan E. West
Roy O. Williams
John L. Wood
Tamotsu Yatabe

Harvard Dental School.

At the annual commencement exercises of Harvard Dental School, held in Cambridge, Mass., June 1918, the degree of Doctor of Dental Medicine was conferred on the following graduates:

| | | | |
|--------------------|--------------------|-------------------------|----------------------|
| Salim Y. Alkazin | Frank W. Davidson | Harvey E. Kimball | A. E. Segal |
| Abraham J. Batal | Hazleton B. Davis | Paul B. LeBaron | Hermon A. Shohet |
| Louis R. Branchaud | George E. Farrell | Harold C. Lockwood | Clifton A. H. Smith |
| Harry D. Brice | L. M. Fine | Neil F. MacDonald | Paul R. Smith |
| Harry A. Burns | Isadore Flink | George D. Malkasian | Harold G. Spooner |
| Raymond P. Cassidy | Louis M. Forbes | Carl W. Maxfield | Geo. A. Staples |
| William J. Clancy | Jacob J. Glazin | Francisco C. Monteagudo | Arthur F. Sullivan |
| Bernard B. Cohen | Wilfred C. Granger | John H. Nugent | Harold E. Tingley |
| John W. Cooke | Myron E. Hale | Jack B. Penn | David F. Wallace |
| Paul W. Crouch | Gordon Hall | Frank I. Rhodes | Henry F. Weston |
| Charles A. Cushing | Orvar J. Hammond | Harold C. Robinson | Paul L. Willson |
| Harold B. Cushing | Philip N. Harris | Alexander Samuels | Roland J. E. Woisard |

College of Physicians and Surgeons.

THE annual commencement exercises of the Dental Department of the College of Physicians and Surgeons were held June 6, 1918, in San Francisco, Calif.

The degree of Doctor of Dental Surgery was conferred on the following graduates:

| | | | |
|-----------------------|---------------------|------------------------|---------------------|
| John V. Buckley | Herbert E. Grieb | Francis A. McCabe | Pauline Schaefer |
| George W. Castle | Riccardo Grosso | Floyd M. McCord | Joseph C. Schneider |
| Harwell W. Coale | Charles I. Hamilton | Francis J. McQuaid | Charles M. Silk |
| Daniel F. Cronin | Albert B. Hanson | Howard H. Mentz | John B. Snell |
| Sidney F. Danne | Francis J. Herz | Alexander G. Middleton | Leo P. Stegeman |
| Frank P. Denham | Eric M. Horner | Yoshimatsu Nakata | Leonard H. Stone |
| Edward E. Driemeyer | Christian Imsland | Cyrus Needles | Vernon A. Usher |
| William H. Eckman | Takeshi Inukai | Warren G. Overpack | Elmo L. Walsh |
| Lauren J. Ennis | Buron D. Kelley | Glen G. Patton | Paul J. Ward |
| Abe Epstein | Charles S. Knoles | John H. Peschong | Irving C. Wells |
| Kenneth T. Fergusson | Edmund J. Leach | Clifford H. Porter | Arthur R. Wienholz |
| Eugene F. Fountain | Conrad H. Lindner | Max Rabinovitch | Harry E. Wilson |
| Victor J. A. M. Gorla | Charles W. Lyman | Russell W. Rogers | Joseph E. Wilson |
| Eugene M. Graham | | | |

Colorado College of Dental Surgery.

At the annual commencement exercises of Colorado College of Dental Surgery, held in Denver, Colo., the degree of Doctor of Dental Surgery was conferred on the following graduates:

| | | | |
|-------------------------|-------------------------|----------------------|------------------------|
| Joseph N. Anderson | James G. Enright | Earl H. Lighthall | Leslie K. Painter |
| William H. Bashier, Jr. | Alonzo L. Faulk | Donald F. Lyon | Archie L. Patterson |
| Ellis J. Baskin | Henry J. French | William R. McCalla | Hugo E. Peterson |
| James E. Bell | William M. Gilmore, Jr. | Roy McConnell | Clyde H. Peach |
| Thomas B. Brattobio | Galen R. Goodson | Fred A. McDaniel | Norton L. Rinehart |
| Charles J. Brown | Roy M. Gordor | Wilbert L. MacKenzie | Donomon Sakamoto |
| George F. Brown | Edwin L. Green | Willie I. Mahurin | Eddie C. Scharman |
| William J. Carlson | Grant Gregorson | George E. Mallott | Stuart C. Sconlor |
| Marion B. Case | Wilbur B. Hards | Gladys E. Mason | William H. Snoddy, Jr. |
| Hung P. Choy | Christian V. Hope | Irving W. Mason | Harry Tracy |
| Raymond J. Clark | Mary W. Hotaling | William F. Mart | Russell P. Tullis |
| James R. Cooper | Eugene C. Kettner | Ernest E. Monson | Jay E. Wheelock |
| Frank C. Daniels | Theodore L. Kozitza | Jacob M. Morris | Clifford F. Wiggins |
| Oliver H. Devitt | Frederick S. Kurtz | Harold E. Nelson | Arthur R. Williams |
| Rex T. Ellington | Chester A. Law | Chester I. Nowlin | Oral B. Wilson |
| Lloyd F. Emal | John C. Lee | Oscar W. Overhuls | Edmund S. Wosnik |

Chicago College of Dental Surgery.

At the annual commencement exercises of the Chicago College of Dental Surgery, held in Chicago, Ill., the degree of Doctor of Dental Surgery was conferred on the following graduates:

| | | | | |
|-------------------|----------------|-----------------|-----------------|------------------|
| E. E. Akan | C. B. Crouch | J. Y. Hurdle | H. O'Dell | H. H. Skolnik |
| G. W. Akerly | L. Dannewitz | E. A. Hussey | G. R. Olsson | W. L. Spencer |
| R. D. Anderson | H. L. Davis | K. Ikeda | F. J. Padt | S. Spira |
| H. Arai | S. Demski | F. A. Jana | Willis Parr | A. H. Stein |
| D. H. Ascher | R. A. Denholm | A. P. Johnson | B. Pawlowski | R. R. Stewart |
| G. Ardery | A. C. Doe | E. M. Jones | A. Phillips | N. A. Stone |

University of Southern California, College of Dentistry.

THE commencement exercises of the College of Dentistry of the University of Southern California, were held on Thursday, June 6, 1918, in the Shrine Auditorium, Los Angeles, Calif.

The commencement oration was delivered by John W. Hancher, D.D., LL.D.

The degree of Doctor of Dental Surgery was conferred by the president of the university, George F. Bovard, A.M., D.D., LL.D., upon the following graduates:

| | | | | |
|-----------------|------------------|---------------------|------------------|-----------------|
| H. H. Alvarez | S. Ballinger | Arthur J. Hook | J. W. McElwee | M. Stillbolt |
| H. S. Adair | W. J. C. Buehren | L. C. Houghwout | N. Nicholson | E. E. Scholz |
| M. Arnot | J. W. Carson | P. Holubek | E. S. Packard | R. B. Stevenson |
| G. K. Brandriff | A. A. Cobb | H. J. Hill | C. R. Pierce | M. H. Thompson |
| H. M. Barnhart | H. P. Dney | M. S. Hayercraft | L. Perner | E. J. Thee |
| C. M. Beebe | O. C. Dobson | J. L. Ironmonger | M. G. Plauk | G. A. Tistaert |
| L. M. Baughman | I. Disraeli | C. W. Jones | R. R. Roberts | H. H. Trumpower |
| K. G. Barnett | E. Ehrenclo | F. W. Krause | G. Ramage | A. C. Vielle |
| T. D. Blake | P. A. Fallgren | R. B. Lichtenwalter | V. J. Smith | D. W. Vanasen |
| G. D. Berryhill | H. A. Ford | W. H. Lorenz | A. A. Smith | L. W. Volin |
| V. M. Blythe | G. F. Garcia | John Menges | A. Sanders | G. W. E. White |
| G. Brown | A. A. Gonzales | J. H. Miller | W. W. Shay | C. M. Woodward |
| H. I. Q. Brown | W. J. Gea | L. H. Murdock | V. Somerville | R. A. Warren |
| S. Bleak | B. A. Garvin | H. L. Mitchell | D. R. Smith | Arlo H. Wells |
| D. E. Brockett | V. J. Gay | H. McElvain | W. S. Sweningsen | J. E. Waters |

University of Maryland, Dental Department.

At the annual commencement exercises of the Dental Department of the University of Maryland, held in Baltimore, Md., 1918, the degree of Doctor of Dental Surgery was conferred on the following graduates:

| | | | |
|----------------------|-------------------|------------------------|-----------------------|
| John E. Abbott | Ralph Fletcher | Clement P. Luongo | John R. Pharr |
| Pedro Badillo, Jr. | Oren H. Gaver | Michael J. McAndrew | Arthur W. Phinney |
| Jos. W. Baker, Jr. | Wm. A. Gray | Frederick J. McCanless | Santiago R. Cubano |
| Harold F. Bradshaw | David Greenberg | Carlos F. Maristany | David A. Rubin |
| George K. Brazill | Abraham Grossman | Chas. B. Martin | Jesse E. Rutrough |
| Clarke S. Bressler | Warder A. Hall | Adam Mielcarek | John L. Sherman |
| Miles S. Buck | Leonard E. Hamel | Douglas M. Milne | Harry Silverberg |
| Geoffrey C. Buehrer | Louis V. Hayes | Norma R. Mitchell | Samuel L. Slovin |
| Cecil K. Charbonneau | Arthur V. Hazlitt | James B. Montgomery | Charles F. Smith |
| Romeo P. Charest | James F. Hines | John A. Mooney | George Cortland Ston |
| Clarence Cohen | Frank A. Hodgdon | William T. Moore | Abraham Sussman |
| Harvard E. Colwell | Isaac H. Horn | Carmen A. Mora | Charles A. Thomas |
| Clarence J. Conway | Walter E. Hutson | Henry VonMurray | John M. Underhill |
| Harold R. Cooper | Henry Joachim | William J. Murray | Robert B. Varden, Jr. |
| Ella B. Cox | Leopold H. Karow | Ignatius Neulander | Dan O. Via |
| Santiago F. Diaz | George A. Kirby | Ernest S. Noel | Joseph E. Welch |
| Crown O. Diehl | Edward L. Knoebel | Edward J. O'Donnell | Lloyd B. Wolverton |
| Aaron Domnitz | George S. Koshi | William H. Parke | Lawrence R. Wolverton |
| Max B. Dunn | Thomas G. Leggo | Richard C. Parks | Harvey U. Yeater |
| James F. Egan | Brownie L. Lewis | Gardner H. Patterson | Max H. Zeisler |
| Wilmer H. Fitch, Jr. | Abe Livingston | | |

University of Michigan, College of Dental Surgery.

THE annual commencement exercises of the College of Dental Surgery of the University of Michigan were held in Ann Arbor, Mich., June 27, 1918.

The commencement address was delivered by Wm. L. Bryan, LL.D., president of Indiana University.

The degree of Doctor of Dental Surgery was conferred on the following graduates:

| | | | |
|---------------------|-----------------------|------------------------|------------------------|
| Victor Adams, 3d | Albertus W. Eksteen | Herman H. Lichtig | Lennox J. Schmidt |
| LaVerne H. Andrews | Frederick H. Essig | John L. Lundberg | Albert A. Seele |
| Ernest N. Bach | Hiram B. Fassett, Jr. | Albert MacDonald | George F. Sheffield |
| Reame L. Bailey | Emerald J. Garlock | Robert D. MacDonald | Matthew O. Sivula |
| Irving E. Baker | Garland G. Gee | Hendrik J. Marais | Hilda M. Smith |
| Roberto C. Barbosa | Kenneth R. Gibson | Karol J. Marcinkiewicz | Henry Starikoff |
| Heman E. Barlow | William J. Goude | Clement P. Martin | Clayton E. Stevens |
| Glenn R. Barnes | John H. Haley | William J. B. Mason | Frank W. Stockton |
| Frank J. Bauman | Gerald G. Hall | Abie R. Melcher | Oliver M. Strong |
| Robert V. Bird | Signe M. Hamalainen | Clarence G. Miller | John W. Sweet |
| George K. Bolender | Bidwell C. Hansen | Donald L. Mitchell | Earl H. Teetzel |
| Albert L. Brock | Frederick J. Henry | Elwood W. Morris | Gerhard E. Thrun |
| James G. Brown | Richard U. Hirwas | John M. O'Leary | Frederick H. Tinsman |
| John F. Bulmer | Paul J. Holt | Carl O. Osborn | Peter C. Treleaven |

| Edmund B. Coughlin | Ephraim Klein | Richard J. Reilly | |

ARMY AND NAVY DENTAL NEWS

Report of Committee on Dentistry.

At the time the United States declared a state of war to exist between this country and Germany, the total number of dental officers was 58—18 captains and 40 first lieutenants—a sufficient number to care for an organization of fifty-odd thousand men. Probably less than 30 of these were stationed in the United States, and they were widely scattered. The law at this time only permitted the commissioning of Dental Reserve Corps officers in the grade of first lieutenant, and there was not a nucleus of a reserve corps to start with, as in the case of the medical service.

In the past year the number of dental officers has increased from 58 in the dental corps of the regular army to 209, in the National Guard to 259, and in the Dental Reserve Corps to 5196—or a sufficient number to supply the quota permitted by law for an army of 5,664,000 men. These officers, as a result of the dental law enacted on October 6, 1917, are distributed in the same grades and percentages within the grades as are allowed for officers of the medical corps of the regular army and National Guard and of the Medical Reserve Corps. The commission of first lieutenant was tendered to 5467 dentists, and 95.1 per cent. accepted—all but 271.

In the rapid development of the dental service, all credit must be given the patriotism of the members of the dental profession, the various preliminary dental examining boards, dental faculties, dental manufacturers, and officers and members of the Preparedness League of American Dentists, an organization which a year ago had a membership of 5000, but today has about 15,000 members, who have paid the membership fee and declared their willingness to render gratuitous service at least one hour a day, when called upon, to assist in making dentally fit the selected man, after he had been certified to by his local board, and previous to his induction into military service.

The official record shows that 166,000 gratuitous dental operations have been performed by the members of this organization. This

organization has been largely responsible for the three dental motor-car ambulances that have been presented to the Surgeon-general of the army. More efficient dental service is expected to result from the fact that dental inspectors are now regularly visiting the cantonments and camps.

The committee has co-operated closely with the deans of dental schools. At a conference held May 12, 1917, attended by deans of thirty-six dental colleges and twenty representatives of state examining boards, with this committee, many details designed to co-ordinate dental activities were agreed upon. At another conference, July 18th, fifty deans discussed with this committee the enlistment of dental students in the enlisted Medical Reserve Corps and their assignment to the inactive list.

Upon the recommendation of this committee a survey of dental and oral hospital physicians was made. An investigation was initiated as to the relationship of trench-mouth disease and oral and general disease. In co-operation with the dental manufacturers, dental instruments and supplies were standardized.

Military instruction was included in the curricula of dental colleges, and special training of applicants for enrollment in the Dental Reserve Corps initiated. Improved courses in the army and navy medical schools for army and navy dental surgeons were recommended.

A school of instruction for dental officers started March 15, 1918, at Camp Greenleaf, Fort Oglethorpe, Ga., with Lieut.-col. Snapp, Dental Corps, as senior instructor. Eighty-five dental officers and enlisted *personnel* are assigned each month to take the two months' course. The first month is given over to 180 hours of general military instruction and training, and the second to 70 hours' special military training, and 110 hours devoted to professional subjects that have a definite relation to general practice of dentistry as it should be conducted in the army.

The United States is the only country giving such extensive training in military and professional subjects to dentists, and this nation has a greater number of dental officers

subject to military call than all other nations combined represented by the term "the Allies."
—*Surgery, Gynecology, and Obstetrics.*

Army Dental Corps.

No more appointments as officers are being made in the army dental reserve corps, excepting among those candidates who were examined prior to September 18, 1917, and who failed to meet the physical requirements and now are being given another opportunity by reason of the modification of the requirements since that time. The dental school at Camp Greenleaf, Fort Oglethorpe, Ga., is busily engaged in preparing both officers and enlisted men for their professional duties with the army, particularly overseas. The course lasts two months, the first month being devoted to military training, the second month to professional instruction, special attention being given to cases emanating from the expeditionary force and from the forces of our allies. Eighty student-officers are selected each month for this instruction, the selections being made mostly from those already in the service, both in the regular dental corps and in the dental reserve corps. Enlisted men are sent to the school for a similar period of training, their course also consisting of a month each of military training and of professional subjects. Enlisted men are selected from dental students, and the instruction they receive at the school is for the purpose of fitting them as dental assistants.

THE convention of the National Dental Association, which was held last week at Chicago, was attended by several delegates from both the army and navy dental corps. The association conferred honorary membership upon Surgeon-general Braisted, of the navy, and Surgeon-general Gorgas and General Noble, of the army.

It is expected that examinations will be held next January to fill places in the dental corps of the regular army. There will be in the neighborhood of 70 vacancies.

—*Army and Navy Register.*

Death of Dental Surgeon Osborne.

THE Navy department has been advised of the death of Dental Surgeon Weeden Edward Osborne, U. S. Navy, who was killed in action in France, June 6th, while attached to the

marines serving with the American Expeditionary Force.

The distinguished service cross was posthumously awarded Dental Surgeon Osborne by the commander-in-chief of the Expeditionary Force, with the following notation in official orders: "Dental Surgeon Weeden D. Osborne, U.S.N., during the advance on Bourresches, France, on Friday, April 6, 1918, at great risk of his life, performed heroic deeds in aiding the wounded. He was struck by a shell while carrying an officer to a place of safety."

Dr. Osborne, who had been with the marines at the front only a few days when the action at Bourresches took place, went into the zone of fire time and again to rescue wounded. He went to the aid of a wounded officer, and had succeeded in carrying him almost out of the range of fire when a shell struck, killing both Osborne and the officer. In reporting his death, his commanding officer wrote: "Having joined this regiment but a few days before, and new to the service, he displayed heroism worthy of its best traditions."

Dental Surgeon Osborne was born in Chicago, November 13, 1892. On May 8, 1917, he was appointed a dental surgeon in the navy, and served at the navy yard, Boston, from June 5, 1917, to December 13, 1917, when he was detached and assigned to duty on the Alabama. On March 30, 1918, he was ordered to report to the commanding officer of a regiment of marines with the American Expeditionary Force in France, and was serving with this regiment at the time of his death. Next of kin, Elizabeth Osborne, sister, Chicago, Ill.—*Army and Navy Register.*

Dentists in the British Army.

MR. PENNEFATHER asked the Under-secretary for War how many qualified dental surgeons now held commissioned rank in the army; how many had been commissioned since March 1, 1918; how many of these had been commissioned from the ranks since that date; and how many were now remaining in the ranks. MR. MACPHERSON: The number of qualified dental surgeons who hold commissions in the army is 640. Of these 92 have received their commissions since March 1st last, including 26 from the ranks. As regards the last part of the question, inquiry is being made. MR. A. F. WHYTE: Does the right honorable gentleman say that there are only 640 dentists for the British army? MR. MACPHERSON: Yes. MR. WHYTE: Scandalous!—*Lancet.*

Promotions.

Dental Reserve Corps.

THE following appointment (promotion) is announced (April 24th):

To be MAJOR: 1st Lieut. Albert W. Marshall.

Announced July 27th:

To be CAPTAINS: 1st Lieuts. Laurence E. Aldrich, John D. Albin, Clarence S. DeLong, Robert L. Donaldson, Henry S. Davis, Howard W. Geiger, Frank F. Happy, Wm. H. Hatcher, Chauncey H. Jones, Ralph O. Leonard, Edwin J. Nestler, Wm. T. Roberts, Howard E. Summers, Herbert J. Schiewetz, Roy G. Strickler, Harold J. Thorne, George P. Taylor, Oscar W. Thompson, Peter J. Wumkes, and Joseph E. Wilson.

Announced August 17th:

To be MAJORS: 1st Lieuts. Wm. H. Potter, Charles S. Jack, John B. Wagoner, and Rumsey F. Rowdybush.

To be CAPTAINS: 1st Lieuts. Allen N. Kearby, Wm. J. Eggleton, Chalmers L. Crist, David S. Smith, Lewis A. Platts, Frederick H. Saunders, Edward H. Raymond, Jr., Bertram S. Rothwell, Wm. S. Sykes, Frederick J. Brockman, James A. Brown, Edwin Shoemaker, Chas. W. Freeman, Wm. W. Irving, John C. Vander Voort, Wm. T. Shannon, Earl C. Barkley, B. Lucien Brun, Beon R. East,

Lloyd Y. Beers, Harry R. Smith, Francis J. Bailey, Earl P. Jones, Alfonso F. Wilbur, Stevens W. Brown, Francis J. Rogers, LeRoy Holland, Harold F. Anderson, Alfred E. Bernstein, Herbert R. Boyd, Mendsay M. Dexter, Doyle B. Morris, and Lynwood Evans.

Assignments.

Army Dental Corps.

Week ending August 3d.

1st Lieut. Wm. B. Stewart from duty at aviation camp, Camp Greene, N. C., to Fairfield, Ohio, aviation school.

Week ending August 17th.

Lieut.-col. Raymond E. Ingalls to Palo Alto, Cal., Camp Fremont, for duty as camp dental surgeon.

1st Lieuts. Neal A. Harper and Edward C. Alley from duty in Eastern department to Fort Oglethorpe, Ga., for instruction.

Dental Reserve Corps.

Week ending August 3d.

Maj. Leonard G. Mitchell to St. Elizabeth's Hospital, Washington, for duty.

Week ending August 17th.

Maj. Crittenden Van Wyck to Fort Oglethorpe, Ga., for instruction.

Preparedness League of American Dentists.

ORGANIZED UNDER THE AUSPICES OF THE N. D. A.

THE DENTAL COMMITTEE OF THE GENERAL MEDICAL BOARD, WHICH IS THE AGENCY FOR THE MEDICAL AND DENTAL PREPAREDNESS IN THIS WAR EMERGENCY, HAS MADE IT POSSIBLE FOR EVERY DENTIST IN THE UNITED STATES TO ASSIST IN THE WORK, UNDER THE SUPERVISION OF THE PREPAREDNESS LEAGUE OF AMERICAN DENTISTS.
HEADQUARTERS AT 50 EAST 42D ST., NEW YORK, N. Y.

Preparedness League Notes and News.

COMMUNICATION FROM PRESIDENT BEACH.

FREE DENTAL SERVICE.

There are a few points about free dental service that should be emphasized at this time.

1. The League requests its members to give each drafted man ONE HOUR of free dental service. This should be given without question as to ability to pay.

When the hour has been completed, the dentist is at liberty to inquire as to the ability of the registrant to pay a fee to have the work completed, should additional service be required. Should he prove himself worthy of further free service, the dentist continues such service in the name of the League.

Such service only is reported to the League.

2. All dental work for which a fee is received from the drafted man is *not* Preparedness League work.

Such service must *not* be reported to the League.

FREE is a word that cannot be qualified and admits of no variation. The charge of a single farthing nullifies the spirit of the League through which free dental service is given.

We have a million of our boys in France. How many of them are suffering from dental ills because you and I did not give them free dental service? Thousands are suffering today because you and I did not do our full duty by them. It is a serious matter, and let us resolve to throw our best efforts into this great work which we alone can do.

Let us fight the enemy with our own

weapons—those with which we are most familiar. As dentists, each one of us can do more to help win the war with the excavator, the engine and the forceps than we could by shouldering a gun and taking a place in the first line trenches.

Each one of us can do this in his own office by giving free dental service to the drafted man. Give it freely and without restraint as one of the great privileges of an American citizen, and let us all be thankful that we are able to do this through the heritage of the greatest birthright given by any nation.

President Wilson has shown us our duty when he said, "An army can win a battle, but it takes a nation to win a war."

I commend to the attention of every member of the League the following letter [viz. Lieut.-col. J. S. Easby-Smith's, to President Beach, as published in the DENTAL COSMOS for August, at page 753], which concisely covers the situation and may be considered as stating the rule to follow. It is most essential that we conform in every particular to the ruling of the War department.

J. W. BEACH.

THE treasurer has from time to time received requests from League workers in various parts of the country, for from fifty to five hundred buttons to be sent for distribution at state or local meetings. Because of action taken at a meeting of the officers held at League Headquarters in January, President Beach presiding, to the effect that buttons should be sent direct from the treasurer's

office and shall serve as his receipt, the treasurer has had no alternative but to abide by the ruling. It is hoped that his position has been understood by those who made requests and that his letter of explanation met with their approval. It is obvious that if allotments of buttons were sent to many meetings in various sections of the country, the League would be compelled to have an investment in buttons amounting to several thousands of dollars. This the funds will not permit.

There is also another serious objection. The button is supplied gratis to members who have joined since the 1st of January 1918. To those who joined before, it is sold for twenty-five cents, which is approximately cost. Without a complete directory of the 5900 older members it is impossible for those handling the buttons at a meeting to know who is entitled to purchase them; therefore, some men might be wearing the buttons who were really not members of the League. The officers, I am sure, might be glad to consider any feasible suggestion by which it would be possible to have buttons at the various meetings. There was delay in sending the buttons in February, because of disappointment in manufacture, but since that time buttons have been sent out regularly each week. Under the present plan, when the member receives a button it is certain that his name has been registered on the official list.

THE following figures show the amount of work done by the Preparedness League to June 1, 1918:

| | |
|---------------------------------|---------|
| Men examined | 84,518 |
| Worked for; reported by card .. | 63,625 |
| Fillings inserted | 180,593 |
| Teeth extracted | 67,247 |
| Plates made | 630 |
| Crowns made | 2,040 |
| Crowns and bridges | 165 |
| Bridges | 885 |
| Prophylaxis treatments | 33,671 |
| Diseased teeth treated | 3,165 |
| Miscellaneous operations | 48,535 |
| Total operations performed | 336,931 |

The above is taken from tabulated statistics made by Major W. A. Heckard.

THE United States now has more than 1,500,000 men under arms, and up to date we have records of work done by the League of approximately 220,000 operations, but if each had done his part this number would have been doubled. Some individual members have performed as many as 150 operations; others (new members), none at all, as they have not yet had the opportunity. Our organization should perform 1,000,000 operations for the men of the next draft.

It is important to keep before the minds of all members the fact that we should devote our energies almost entirely to men qualified for general military service. These are the men who will do the actual fighting, and who must live in the trenches, and who consequently are more subject to sickness and infection.

R. OTTOLENGUI,
Publicity Committee.

SPECIAL NOTICE.

*VACANCIES TO BE FILLED IN THE EXAMINING CORPS
OF THE PATENT OFFICE.*

DEPARTMENT OF THE INTERIOR
UNITED STATES PATENT OFFICE
WASHINGTON, D. C.

JULY 15, 1918.

TO THE PUBLISHER OF THE DENTAL COSMOS:

Will you kindly call attention through your columns to the need for technically trained persons for the examining corps of the Patent Office. Men or women are desired who have a scientific education, particularly in higher mathematics, chemistry, physics, and French or German, and who are not subject to the draft for military service. Engineering or teaching experience in addition to the above is valued. The entrance salary is \$1500.

Examinations for the position of assistant examiner are held frequently by the Civil Service Commission at many points in the United States. Details of the examination, places of holding the same, etc., may be had upon application to the Civil Service Commission, Washington, D. C., or to this office.

Should the necessity therefor arise, temporary appointments of qualified persons may be made pending their taking the Civil Service examination. Application for such appointment should be made to this office.

Very truly yours,

J. S. NEWTON,
Commissioner of Patents.

SOCIETY NOTES AND ANNOUNCEMENTS

NOTICES should reach the Office of the DENTAL COSMOS *not later* than the 11th or 12th of the month preceding that of publication.

Northeastern Dental Association.

THE twenty-fourth annual meeting of the Northeastern Dental Association will be held at the Narragansett Hotel, Providence, R. I., on October 10, 11, and 12, 1918.

ALVIN A. HUNT, *Sec'y*,
Hartford, Conn.

Preparedness League of American Dentists, Cleveland Unit.

ELECTION OF OFFICERS.

At a meeting of the Cleveland Unit of the Preparedness League of American Dentists the following officers were elected: E. H. Shannon, president; Ira M. Saum, vice-president; J. Gordon Lowe, secretary-treasurer. Executive Council—F. M. Casto, G. E. Bishop, H. C. Kenyon, G. D. Lovett, D. H. Ziegler, and H. R. C. Wilson.

J. GORDON LOWE, *Sec'y-Treasurer*,
719 Rose Bldg., Cleveland, Ohio.

Susquehanna Dental Association of Pennsylvania.

THE fifty-fifth annual meeting of the Susquehanna Dental Association of Pennsylvania will be held at Hotel Casey, Scranton, Pa., October 9, 10, and 11, 1918.

GEO. C. KNOX, *Rec. Sec'y*,
300-301 Dime Bk. Bldg., Scranton, Pa.

Massachusetts Board of Examiners.

A MEETING of the Massachusetts Board of Dental Examiners will be held in Boston, Mass., October 21 to 25, inclusive, 1918, for the examination of candidates for registration. All applications must be in the hands of the secretary on or before October 11th. For further information address

GEORGE H. PAYNE, *Sec'y*,
29 Commonwealth ave., Boston, Mass.

Forsyth Dental Infirmary for Children.

NEW DEPARTMENT—LIBRARY AND MUSEUM.

THE trustees and director of the Forsyth Dental Infirmary for Children have authorized the creation of a new department, to be known as the "Library and Museum." They solicit from the dental profession contributions of books and dental periodicals, particularly those out of print and not readily obtainable by purchase; also specimens of dental abnormalities, casts, or specimens of unusual structures of dental interest, for all of which permanent acknowledgment will be given.

FREDERICK A. KEYES, D.M.D.,
Librarian and Curator of Museum.

National Mouth Hygiene Association.

DEPARTMENT OF EXTENSION LECTURES.

A COMPLETE lecture set, consisting of full manuscript and thirty-six specially selected and prepared lantern slides covering the subject of Mouth Hygiene, is furnished by this association to members of state dental societies and others who may be considered as qualified to present the subject on the lecture platform.

For rental and sale terms and other particulars address the undersigned.

EDWIN N. KENT,
Director of Extension Lectures,
330 Dartmouth st., Boston, Mass.

DR. GEORGE A. MAXFIELD.

ORIGINAL COMMUNICATIONS

Exercises for the Development of the Muscles of the Face, with a View to Increasing Their Functional Activity.

By ALFRED PAUL ROGERS, D.D.S., Boston, Mass.

[COPYRIGHTED 1918 BY ALFRED PAUL ROGERS.]

(Read before the Eastern Association of the Graduates of the Angle School of Orthodontia,
May 6, 1918.)

THE study of the human face is intensely fascinating. The least attentive of us at times enjoys observing and speculating on faces, in a more or less thoughtful way, during those moments when the mind is unconcerned with other interests. Unconsciously, sometimes, we are classifying them as strong or weak, attractive or unattractive; and usually this observation occurs without giving much thought to the factors responsible for the various conditions.

The ordinary observer, if he speculates at all upon the faces which he sees, is apt to hold the mental condition of the subject of his observation responsible in a large degree for the strength, weakness, or peculiarities of development. Many children have been hastily judged to be defective when this judgment has been based upon the undeveloped countenance sometimes typified by the open mouth and the toneless muscles. This may be

because the observer has been so engrossed by other things that he has neglected to study the face from a physiological and anatomical standpoint. Possibly he has allowed himself to base his easy judgment upon the assumption that psychologic influences are responsible for some developments to him otherwise unexplainable. His common knowledge of the fundamental functions of the human face has been too limited to permit satisfactory judgment.

As a profession, the anatomical and physiological study of the deeper parts of the face have absorbed our attention almost to the complete exclusion of the more superficial. The alterations that are sometimes effected in facial contour have aroused in us, at times, a high degree of satisfaction, yet many of these changes in outline do not carry with them the guarantee that an establishment of function in general has been attained.

It is a simple matter for us to produce these pleasing outward changes, and it is a temptation to us sometimes to become flattered by such easy conquest. These changes are often brought about by those who employ the most unscientific methods, and the apparent ease with which results of this nature are obtained conduces to a weakness in the system of practice generally. Many of these changes are but temporary, and do not carry with them the establishment of complete function.

The narrowness of our view is by no means surprising, since we started not many years ago as odontologists—literally speaking, “tooth-straighteners.” Although this science has grown broadly until physiological and biological considerations of the parts immediately adjacent to the teeth have been deeply studied, there is yet room for a greater broadening of our conception.

Some of our profession still in their mental conception linger near the narrow horizon furnished by the teeth alone, and make their plans with reference only to those non-functional organs. I am reminded in this connection of a most excellent paper written recently by Dr. A. LeRoy Johnson, setting forth the biological reason why we must consider more thoroughly the surrounding tissues in their relation to the teeth, and clearly showing us which tissues are to be considered functional and which are not to be so regarded.

The present attempt on my part is an endeavor to elucidate some of the difficulties furnished by the abnormal condition and behavior of the soft tissues of the face—stumblingblocks which have annoyed us greatly at times, often hindering us in our conscientious efforts toward attainment of the best results. This paper is given as the result of a perhaps dilatory awakening after some years of thought and experience growing out of an active practice. The observations here noted are possibly not entirely scientific. They may be considered the results of both empiricism and method—not so entirely the result of method as perhaps they would have been had there been time

for a more systematic tabulation of observations and facts.

The odontologist has handicapped himself in the past by trying to gain results solely through his own efforts instead of pointing the way to personal self-improvement by the patient, ignoring the physiological forces which work under the direction of the mind in stimulating functional activity of the various organs which are essential to his complete success. We have not employed sufficiently such a useful instrumentality. We have allowed ourselves to become baffled by the weakness of unused or improperly used forces of the soft tissues of the face.

IMPORTANCE OF PROPER MUSCLE FUNCTION IN THE CORRECTION OF MALOCCLUSION.

My reason, then, for bringing before you the subject of facial muscles and their culture is the very special one that I share, first, the belief that the culture of the muscles of mastication and the so-called muscles of expression is of paramount importance when considered in relation to their influence upon the developing bony structure beneath them. The successful treatment of many cases of malocclusion is dependent upon an understanding of the muscular tissues of the face and the development of their functional activity. Strong, well-controlled muscles are valuable in the maintenance of occlusion when it has been established. Muscle training is the best and most rational means for overcoming various facial muscular habits, such, for instance, as that of mouth-breathing. Another reason why I am glad to read this paper is that opportunity is given me to present to you a method for the culture of these muscles and for the encouragement of their normal functioning. All that I shall say to you has been verified by my personal experience in practice, and I can assure you that seldom has anything given me quite so much satisfaction, and promised so much for the future treatment, as the development of the muscular tissues of the face in conjunction with a certain simplicity

of mechanical construction employed for the stimulation of the other tissues.

In fact, viewing the practice of orthodontia from the standpoint which I now do, exclusion of some of our methods will be found essential, and the employment of more simple mechanical devices substituted in their stead. The old and crude conception of orthodontia which permits the orthodontist to admit that he is a regulator of teeth, and that his chief reliance lies in the expansion arch and ligatures, has no place in the plan of procedure that is designed to fit in with the practice based upon the development of normal functions of all the facial organs. This form of appliance hinders the developing influence of many of these muscles. It is a frequent producer of dangerous and long-enduring muscular habits. It rather discourages the performance of the normal activity of the muscles within the radius of its influence. If you will turn to your textbooks on Orthodontia and study the illustrations of the expansion arch and ligatures you can readily make your comparisons. It will not be long, I believe, before the expansion arch will be used only infrequently. Something like this attitude is bound to become general when deeper study is made into the possibilities of development attending systematic efforts along rational lines of functional development.

Many facial maldevelopments in common with other bodily abnormalities are due to improper and feeble functioning from early childhood. There are many cases offering a definite resistance to the orthodontist in securing desired results. You have seen dozens of children mouth-breathers who have been operated upon by skilled surgeons and orthodontists, and who are still mouth-breathers, with untrained muscles of respiration, unused facial muscles, with weak wills in relation to these organs. These are things we need to think and talk about, in order to become, in the quickest way, of the most use to our patients.

From the orthodontist's standpoint the muscles of expression are much more than the name implies, for they are the

muscles which, if not properly developed, are apt to give evidence of lack of facial harmony. They are the muscles which, if not under proper nervous control, are likely to assume various forms and abnormalities in action, resulting in malformation of the fragile osseous structure of the face in young and growing children. My observation teaches me that uncultured muscles are apt to be the ones that assume unhealthy habits. It is certainly true that uncultured muscles lack tone, and in lacking tone they do not respond to normal stimuli with the same degree of activity and precision that is found in those that are under proper control. Moreover, it is well for us to remember that muscles tend to stay in the position in which they do their greatest and hardest work. I have seen distorted parts become permanently so, by the habitual tension of one small muscle.

If you will turn again to the textbooks on Anatomy and Physiology you will find some interesting chapters on myology and physiology of muscular tissue, and you will note with greater interest and a broader understanding the marvelous functional system here developed, and capable of serving us as an ally instead of an enemy.

PHYSIOLOGY OF MUSCULAR TISSUE.

Before entering into the consideration of the practical application of the views which I am to present to you it is logical for us to review briefly some physiological facts. We learn that the movements of various parts and organs of the body are brought about by a special histological structure, and possess the special function of contracting in length under the influence of a proper stimulus. Our study is based solely upon the small group of skeletal muscles whose structural arrangement and mechanical action are based upon a common plan, and are to be understood as being chiefly masticatory and facial. The cells of which these skeletal muscles are composed are long, narrow, and striated. They differ somewhat from the structure of other

muscles of the body, and in differing in structure they differ in function. The principal difference is that the striated muscle is under direct control of the central nervous system.

A typical skeletal muscle consists of a fleshy mass enveloped in a membranous aponeurosis or fascia, and provided at its end attachments with tendinous connections to either the bone or cartilage, or, as in the case of the myoides, to fascia and skin. Each one of these muscles is made up of a number of fasciculi, arranged in such a way as to give form corresponding to the function of that particular muscle.

These bundles of small fibers are held together by a delicate connective tissue called the perimysium, continuous with the surrounding fascia which incloses the muscles. Each smaller bundle is composed of a number of narrow elongated muscle cells or fibers held together by a still more delicate connective tissue *i.e.* the perimysium internum. This delicate membrane is in turn connected with the smaller cells of the muscle, and also with the external perimysium. Thus it will be seen that muscles are highly organized even when considered in connection with muscular tissue alone, and that they are essentially organized as the agents of motor activity when nervous, vascular, and lymphatic systems are considered.

It is interesting for our purpose to note how generously each muscle is supplied with nerve tissue, which, after entering the substance of the muscle, separates into smaller and smaller branches until ultimately it terminates in small fibers in each muscle cell.

Now, we have seen that the muscles may be regarded as organs endowed with particular properties; that being supplied with nerve tissue they are designed for definite movement in response to some stimulus, and that there is every reason to believe that the purpose of nature was to effect co-ordination of action through the elaborate though delicate nerve supply.

Muscles in their physiological condition require for their maintenance and

their activity a very large amount of nutritive material, since they are in a measure heat-producing organs. There is a certain amount of breaking down and rebuilding, and thus the lymphatic system is found as intricate and complete as the other systems. The lymph capillaries relate to the muscle fibers as does the nerve tissue, and give off short transverse branches which immediately break off in the capillary network surrounding the muscle fibers. It will be seen that they are admirably constructed for the work of repair and waste. The nutritive material passes through the capillary wall into the lymph space through the sarcolemma where it comes into the living tissue. The waste products pass first into the lymph, then into the blood stream, whence they are carried away by the eliminating organs.

The physiologist tells us that the properties of the muscles are their irritability, contractility, elasticity, and tonicity. It will not be necessary for us to study these properties, for we know their significance in a general way, but it will be interesting for us to make reference to the mode of muscle stimulation in order to complete our conception of what muscles are, what they are for, and how they can best be kept in normal condition.

The stimuli are furnished by action of the nerve impulses transmitted by nerves from the central system to the muscles. Each muscle impulse is a normal physiologic stimulus, and is under direct control of the will.

Muscle culture, then, by its very nature is also mental culture, because it calls forth repeated efforts of the will, and the exercise of the function of the brain and the function of the muscle is, I believe, mutually beneficial.

Prof. F. Stanley Hall, an investigator of unusual merit, says: "The muscles are in a most intimate and peculiar sense the organs of the will. They have built all the roads, cities, and machines in the world, written all the books, spoken all the words, and in fact have done everything that man has accomplished with matter. If they are undeveloped, or

grow relaxed and flabby, the dreadful chasm between good intentions and their execution is liable to appear and widen. Character might, in a sense, be defined as a plexus of motor habits." Is not this testimony of a man whose life has been spent in investigation full of significance for us?

Doubtless any one of you can recall to mind certain patients whose facial muscles are so flabby and inert that it is difficult to define one muscle from another. In my investigation of this subject I have discovered many faces in which pronounced malocclusion exists where there is little control of various groups of muscles. I have found many patients who are unable upon command to throw any considerable effort into the masseter muscles. Others I have found who are unable to control the pterygoid muscles upon the first few attempts, but after repeated efforts are able to operate, at will, both of these groups. It has further been found that groups of muscles which have not been subjugated to the control of the central nervous powers as they should, fail to give evidence of their complete development. In some instances they even cease to respond to mental stimuli save after repeated and prolonged effort.

The motor activities with which we are most concerned should be performed with exactness and precision of both mind and muscle. The hands of a pianist or violinist show excellent examples of a high degree of muscle culture. Many have an erroneous idea that the muscles become excessively large under continuous stimulation, but each muscle or muscle group has imposed upon it its limitation in strength and size. It is, therefore, not to be supposed that all men can develop muscles to compare with those of a Samson, but it is true that all muscles under a sufficient degree of normal stimulation, providing the health of the individual is sufficient, can be developed into strong and efficient organs.

We can readily understand that the motor efficiency of the parts of the body upon which we are directing our atten-

tion depends upon the ability of our patients to gradually attain the faculty of directing mental stimuli in sufficient amounts to effect their development. It is because of the law of mental growth known as repetition that the orthodontist realizes his greatest encouragement regarding this phase of his work—*because the things that are done from choice tend to become spontaneous if often repeated*. Therefore, the ability of the muscles to continue the performance of their full functions after repeated efforts of the will is assured by their educated state. It is well known that the growth and strength of the alveolar tissue depends upon proper function. If we can by this means increase the strength and life of this tissue, the teeth will have a stronger environment and a prolonged usefulness.

In the process of the realization of our ambition along these lines we shall meet with many discouraging and seemingly well-nigh unsurmountable difficulties, but we must be fully mindful that nothing of such importance can develop rapidly and at the same time accurately. Many youths will pass from under our care not much affected by our ministrations and advice, but on the other hand many of them will realize that the development of the functions of the face can be only a blessing to them.

In suggesting and recommending this form of investigation I want to say emphatically that it will be well for us to proceed with caution. I do not know that in this paper it will be possible for me to point out all the dangers, since I may not know them all, but it is possible for me to point out the seriousness of the undertaking and to urge careful consideration and study before attempts are made to develop functional activity of any tissue in which we are interested.

The student of this work must be conversant with physiology. He must be always on the watch against the establishment of harmful habits. He must be careful not to overstimulate long-unused muscles. He must be careful not to expect great results from little effort.

RELATION OF MUSCULAR FUNCTION TO MOUTH-BREATHING.

It is my belief drawn from experience that the great problem of curing or overcoming the habit of mouth-breathing is through the exercise of muscular function. We are all perfectly familiar with cases operated upon by the rhinologist where the removal of the nasal obstruction, adenoids, and tonsils has not been followed by the beneficial results promised. In the case of individuals who have failed to receive the hoped-for results the muscles will be found to lack tone

FIG. 1.

and development. Proper, systematic exercise alone will be found to do more than any other thing to produce harmonious development.

I am reminded of one particularly hopeless case in which I have been fortunate enough to stimulate the patient's interest to the degree that she is following my instructions faithfully, and with excellent results. During a long period of acquaintance I had never once observed this child with her mouth closed, but after a few months of conscientious effort on the part of mother and child we are delighted to find the vicious habit disappearing, and a fine symmetrical facial contour developing.

Another case of persistent open bite,

caused by lack of tone of the facial muscles, particularly the orbicularis oris, where mechanical retention failed to give complete satisfaction, has now remained satisfactorily closed after the muscles of the mouth were developed sufficiently to act as a balance to the forces behind.

We shall find when we turn to the needs of our patients that our work is confined chiefly to a group of small muscles, and must therefore differ in some degree from the methods that would be used to develop those of the other parts of the body. In general it will be noticed that the muscles of mastication and those of expression have been used only moderately by our patients, and our first lesson must be to learn not to overstimulate them.

It has been my custom in beginning with a new patient to insist that the exercise be done at stated intervals and under the supervision of an older person who has been carefully instructed. More patience is required in some cases than in others. It will soon be learned that the control of motor life in the tissues of the face will in a large measure overcome the so common tendency to bolting their food without proper mastication. In my personal work with patients I deem it one of the essentials first to strengthen the muscles of mastication, in order that whenever occasion requires they may be used more vigorously, thus still further increasing their usefulness in that their capacity for hard work has been greatly increased.

CONSIDERATION OF THE VARIOUS MUSCLE GROUPS.

We are led now to a brief consideration of the muscle groups. Pictures of these from Gray's and Cunningham's *Anatomies* will be thrown upon the screen. Those which we shall first consider are the ones in which, for logical reasons, we are most interested, namely, the pterygeid, masseter, and temporal muscles. Later we shall refer to the muscles of expression, which consist of the levators labii, depressors labii, and zygomaticus muscles. The platysma myoides will be

given separate consideration, which it is of considerable importance to our work that they should receive.

MUSCLES OF MASTICATION.

The interesting thing about the muscles of mastication will be found not

relation between the pterygoid fossa and the plates and the head of the condyle between which some of these small fibers are stretched: also the relation between the external plates and the inner angle of the ramus, where other fibers are stretched. It will be readily recognized that if from early childhood the activity

FIG. 2.

only in their shape, but in their attachments. The pterygoid muscles are particularly interesting to us from this standpoint, as they will be seen to be attached to points of great advantage when their function, the control of the mandible, is considered. In order to gain a true conception of their relations we will make a brief study of the under surface of the human skull.

It is well to notice (see Fig. 1) the

of these muscles has been hampered on account of distal position of the mandible, one of the first duties of the orthodontist, in undertaking treatment of class II cases, is to direct sufficient stimulation to these muscles to accustom them to the altered position which they will assume when the mandible occupies its normal position. It may be well at this point for me to emphasize the importance of the early exercise of these muscles in

cases where it is required. This is true even where intermaxillary elastics are proposed, or where inclined planes upon the anterior teeth are contemplated. Particularly is this necessary when we contemplate the changes that take place in the glenoid fossa as the child grows to maturity. (Fig. 2.)

You have all experienced, in treating younger cases, the voluntary shifting of

strain, through the apparatus, on the molars and incisors, and according to my experience is not good treatment.

It seems to me that it is much safer when possible to train these muscles through exercise so that the proper position of the mandible is more readily taken when opportunity is given to it. It not only relieves strain upon the teeth, but avoids many other complications.

FIG. 3.

the mandible upon the removal of the interference frequently caused by an abnormal narrow upper arch, or perhaps the interference of upper lateral incisors in lingual position. This voluntary change does not take place so readily in older children for the reason that the glenoid fossa has become of such shape as to discourage the pterygoid muscles in overcoming the handicap. I am also reminded that frequently we see cases under treatment where two or three elastics are attached to teeth on each side of the mouth in order to correct a distal occlusion. This practice brings tremendous

It is not to be supposed that I advocate the entire abandonment of intermaxillary elastics during the present state of our experience. These still remain valuable adjuncts, and it will be a long time, I think, before we shall entirely discard them. Their use, however, should be carefully studied and the application made as light as possible.

The exercise of the pterygoid muscles previous to the application of inclined planes on the anterior teeth I have found of great service, as the mandible may be readily trained to take the forward position, thus avoiding the strain which is

usually heaped upon the incisors when this form of apparatus is placed upon them without taking this precaution.

Fig. 3 gives a very comprehensive view of the external pterygoid muscles, showing the direction of their fibers and emphasizing the importance of the observations I have just made. It will be seen that these muscles may be regarded as the intermaxillary elastics of nature, and I think you will agree with me that when they are trained to perform their function accurately and well they may be expected to furnish a guarantee of unusual merit for the permanence of our treatment.

FIG. 4.

EXERCISES FOR THE MUSCLES OF
MASTICATION.

The exercise for these muscles consists in throwing the mandible forward as shown in Fig. 4. The patient requiring this form of exercise is instructed to throw the mandible forward as far as possible, or until the lower anterior teeth are placed in labial occlusion to the uppers; it is held there for ten seconds and then slightly relaxed. The effort is then repeated as many times as the na-

ture of the case requires. In some cases this will at first be found impossible, but after practice the work becomes easy. This form of exercise is usually pre-

FIG. 5.

scribed in cases of distal occlusion, and the operator must here be careful in his diagnosis.

The liability in overstimulating these muscles in the very young will be obvious

to any of you who have thought at all upon this subject. Very little of this for some patients, as shown in Fig. 5. In this instance there is a combination

FIG. 6.

FIG. 7.

FIG. 8.

exercise is sufficient in the case of some, while in others it is almost impossible to overdo it. Still further efforts are made

of a posture exercise of unusual merit, and the pterygoid exercise. The patient is directed, after taking the position here

illustrated, to stretch the point of the chin upward as far as possible, bringing vigorous strain upon the platysma myoides. Fig. 6 represents a child in great need of the exercise for the pterygoid muscles first, and all the other muscles of the face when occlusion has been established, or during the process of its establishment. Fig. 7 represents the same child undergoing the exercise of the pterygoid muscles.

and relaxing the groups of muscles shown in Fig. 9.

In many cases it will be found that the ability to contract these muscles is very slight indeed, but after a few months' practice the operator is gratified to find greatly increased tone and improved control, as is shown by the ability to contract and relax the muscles. All efforts must be made with great concentration, and must be complete in their

FIG. 9.

Fig. 8 gives an example of the improved condition after a few months of this exercise in a case of class II. The only apparatus used in this instance was the upper lingual wire, through whose instrumentality the interference of a narrowed arch was removed. After the ability to place the teeth in proper relation had been acquired, the patient had another exercise added—that of the temporal and masseter muscles. This exercise consists of holding the teeth firmly in occlusion and alternately contracting

relaxation and their contraction. The ability to completely relax these muscles between each impulse is important to secure, as muscles exercised in this manner, for physiological reasons, grow stronger much more quickly.

Fig. 10 shows a child in the act of stimulating these groups. The position of the fingers is useful in the beginning, in teaching the child to detect the movements.

Fig. 11 shows a form of exercise for these muscles which may be given when

it is not wise to place the teeth in occlusion, and is used sometimes in anticipation of the exercise just described. It is performed by directing the child to pit

lingual wire the upper arch was expanded until the lingual occlusion was

disposed of. When this point of development was reached, as will be readily

FIG. 12.

ten years of age, who was suffering from lingual occlusion of the upper bicusps and molars. By the use of the

understood, the condition of the open bite was much exaggerated, and this is when the patient was instructed in the use of

the exercise of the temporal and masseter muscles.

The figure on the right represents the same case a few months later, showing the correction of the open bite brought about solely by this means. The child's ability to masticate has been wonderfully improved, and it may be said in passing that the high degree of nervous irritability present at the start has largely dis-

lack tone, or are not under control of the nervous system, they are the muscles which are most apt to place perplexing problems before the orthodontist.

Most of these muscles are in some way attached to the orbicularis oris, and when we have a general lack of tone in all these muscles there is sure to be lack of balance between them and the inner forces, such as the tongue. There are numerous ex-

FIG. 13.

appeared, and the child shows a generally improved physical condition.

MUSCLES OF EXPRESSION.

Fig. 13 gives a general view of the lesser groups of muscles, but none the less important to the orthodontist. They consist of the levator labii, depressor labii, zygomaticus, orbicularis oris, and platysma myoides. The names of some of these muscles indicate their function and are perfectly well known. If they

exercised which can be used for stimulation of these groups, but it is not my purpose in this paper to deal particularly with these exercises. It might be well, however, for us to direct our attention to the orbicularis oris. Many of us, no doubt, have had difficulty in retaining the upper incisors in correct position. It is necessary, frequently, to apply retaining apparatus to effect this purpose, but if, in the meantime, this muscle has not become strengthened, in case it originally lacked tone, upon the removal of the re-

taining apparatus the incisors again become protuded. I have several cases in my practice where better results have been obtained in cases of this character

FIG. 14.

strengthening this muscle consists in pitting the strength of the thumb and first finger, or two first fingers, against the contractile forces of this muscle. Care must be taken in the performance of this exercise not to stretch but rather to contract the muscle around the slightly separated fingers. Thus ensues a contest of strength between the orbicularis oris and the muscles of the fingers. The contracted orbicularis oris can be readily seen during the exercise.

EXERCISE FOR GENERAL FACIAL DEVELOPMENT.

It is frequently found necessary to prescribe a tonic exercise which I have termed the exercise for general facial development. This exercise influences not only the orbicularis oris, but also the buccinator and all the small ribbon muscles which enter into combination with the orbicularis oris. It consists in the use of warm water at a temperature which is bearable to the mucous membrane of the mouth and in which has been dissolved a small portion of bicarbonate of soda. The patient is directed to take a sip of this solution closing the teeth firmly in position, and with great energy forcing the liquid from the lingual cavity into the buccal. The exercise is usually performed five times morning and night. The patient is directed to continue each exercise until the muscles are slightly fatigued. A not unpleasant aching sensation is the indicator of the successful effort. The heated liquid adds a distinct advantage to this exercise as it has a tendency to dilate the bloodvessels, thus producing a more copious supply of nutritive material. At the termination of this exercise the face will be found to glow with warmth.

THE PLATYSMA MYOIDES.

without any retaining apparatus at all. One particularly obstinate case yielded to treatment applied for the strengthening of the orbicularis oris muscle.

A valuable exercise I have found for

The platysma myoides muscle is one which to my mind is of great importance when considering the correction of faults in the facial muscular development. This muscle has no bony attachments, but is inserted in the fascia and skin of

FIG. 15.

FIG. 16.

the pectoral and deltoid muscles of the chest and upper shoulder at one end, and at its facial extremity is inserted by many fibers into the orbicularis oris and some of the other muscles upon or near their entrance into the orbicularis oris. It will then be seen that, if this muscle is contracted in its length by improper posture of the patient, it has a tendency to stretch the weakened muscles of the

The child is then directed to relax somewhat, bringing the head and arms to erect position—then repeating the impulse. This exercise is done at first a few times in the morning upon arising, and a few times before retiring, and is increased until the child is able to do it from sixty to one hundred times a day. It is important in this exercise that the child be not allowed to curve the vertebræ

FIG. 17.

face in directions which bring gentle but harmful pressure upon the fragile bony structure of the child's face.

The exercise for this muscle is found in the general posture exercise illustrated in Fig. 5, which consists in having the patient stand with feet together, hips slightly thrown back, then directing the child, with head thrown back, to look straight to the zenith, at the same time drawing in the abdominal wall, and, turning the palms of the hands outward, making a slow and positive stretching motion with the tips of the fingers and the point of the chin.

so that the back represents much concavity. To avoid this the child is directed, when drawing in the abdominal wall, to tighten at the same time the muscles of the buttocks.

Fig. 14 shows a subject much in need of this kind of treatment, and one in which one month of faithful practice has shown most gratifying results.

In Fig. 15 the profile on the left shows a child with slight distal occlusion. It will be noticed that the muscles around the mouth are poorly developed, and evidently not under proper nervous control. The picture on the right shows this same

patient after completion of the treatment and having now very satisfactory muscular development. The figure on the right also shows the improved contour and the more normal nervous control of the muscles of the face. This patient has developed an unusually fine set of masticatory muscles, whereas when the case was started these muscles showed very little development.

Fig. 16 on the left illustrates the facial contour of a child who was treated for several years by a careful orthodontist. Repeated efforts at retention were of no avail until after I placed the child

defined masseter muscles. The nervous contraction of the muscles at the point of the chin has disappeared, and the orbicularis oris has assumed a much more normal appearance. The figure on the right shows the profile a few months later, and after exercise for general development had been practiced. The points to which I would call your attention are again the masseter region, the lower surface of the mandible, the lips, and then the face in general.

It is impossible for me to describe the improvement in the character of the muscular tissue between the periods rep-

FIG. 18.

under carefully prescribed exercises. It will be interesting, I am sure, for you to know that there is no recurrence of the protrusion of the upper and lower incisors, although there has been no mechanical appliance in the mouth for their retention.

I should like to direct your attention to one or two points in this child's face which cannot fail to be of interest. If we look at the region of the masseter muscle, in the picture on the left we notice that it is not well defined—that at the symphysis there is a flattening and puckering of the tissue. It will also be apparent that great lack of tone is evident in the orbicularis oris muscle. In the picture on the right will be seen the well-

resented by these two pictures. At present, the feeling of health and strength shows a marked contrast between the feeling of flabbiness and inertia which was so noticeable upon a digital examination when treatment was begun. Fig. 17 shows the front view of this child, and gives us a very good idea of the value of the exercise for the orbicularis oris. It will be noticed that this muscle seems much firmer—we might speak of it as having been condensed, the aperture being considerably smaller.

The case illustrated in Fig. 18 is one which calls for the development of the facial muscles, and represents a class with which we are all dealing daily. This treatment consists of general ex-

pansion of both arches by means of the junior pin-and-tube appliance on the upper and the lingual wire on the lower. After sufficient expansion was obtained to assure unhampered eruption of the per-

FIG. 19.

manent teeth, the child was instructed in the exercise of the masseter and temporal muscles. The upper junior pin-and-tube appliance was then removed. The lower lingual wire alone remains to preserve the development. No attempts

ample of many others treated in like manner.

Fig. 19 illustrates the positions taken by the various forms of appliances—the expansion arch, pin-and-tube appliance, and lingual wire. It will be seen from study of this diagram that the arrows indicate the tendency toward the movement under use of each of the three different systems. The pin-and-tube appliance has its advantage over the expansion arch in that it has compensating force which may be used in the correction of the apical position of the teeth. The lingual wire has great advantage when cases under treatment are to receive the full value of functional exercise. The movements of the teeth, of course, must be very slow, and the activity of the muscles increased as much as possible.

It will be seen that those muscles which come in contact with the labial and buccal surfaces of the teeth are unhampered in their normal influence upon the teeth themselves; and in this manner apical development is secured. The proper use of the lingual wire, supple-

FIG. 20.

whatever were made to correct the individual positions of the upper incisors. They gradually assumed their correct positions under the activity of normal function increased by the muscles of mastication. I offer this case as an ex-

mented, as suggested before, by activity of the muscles, has in my practice given little evidence of the tendency to tip the teeth. Of course, if the forces that are applied are unbalanced, or in other words, if the force of the lingual wire

is so great as to overcome the influence of the muscles, tipping may be expected; but the essential thing is to proceed so slowly that the influence of the muscles

FIG. 21.

is not overcome. These methods are particularly applicable to the young, but may in older cases be used with considerable success. This may be seen in Fig. 20,

FIG. 22.

where the case of a child fourteen years of age was corrected with the use of lingual wires alone, together with a fair degree of exercise.

Fig. 21 illustrates the lingual wire familiar to all of us, but deserving more

study and attention by the profession in general. Its simplicity and cleanliness alone should recommend it to more universal study and use.

Fig. 22 shows the anatomical area over which the muscles have their primary influence, and it seems to me a regrettable fact that orthodontists in general find it necessary to fill this space with unyielding and irritating appliances such

FIG. 23.

as so frequently are seen in the employment of expansion arches and ligatures. I should not wish to be understood as suggesting that the usefulness of the expansion arch has entirely disappeared, but I do make the assertion that its usefulness is limited, and is becoming more so.

I am ever reminded in my efforts for my patients that the mission of the orthodontist is not merely that of the "tooth-

straightener," but he must be a developer of the bony tissue which forms the framework for the organs of mastication; that his mission is not to stop when he has placed the teeth in some kind of occlusion; that it is his duty, in order to perform his work well, to strengthen all surrounding tissue that has to do directly or indirectly with the development of the face.

Our guardianship of little children is not complete until we, as orthodontists, gain a broad conception of the scope of our science, and minister to the young under our care until their faces represent not only the ideal from the standpoint of the function of mastication, but also the ideal of perfection in contour and strength which it is their right to enjoy. We cannot do better in reflecting upon

our professional work than to keep in mind the physical perfection of primitive man, as illustrated in Fig. 23, Cyrus E. Dallin's "Appeal to the Great Spirit." While we do not turn to him for ideals in many things, yet we cannot escape from him when we seek the ideal of physical strength and endurance.

Careful Technique the Greatest Factor in the Construction of Full Upper and Lower Dentures.

By ALEXANDER H. PATERSON, D.D.S., Baltimore, Md.,

PROFESSOR OF TECHNICS, UNIVERSITY OF MARYLAND, DENTAL DEPARTMENT, BALTIMORE.

(Read before Maryland State Dental Society, Baltimore, June 6, 1918.)

I CLAIM no credit for anything original in this essay. What I am presenting at this time I have gained from reading, from observation in my practice, and through Dr. Hall's instructions for the past three years.

I am often reminded of a statement made by my professor in physics during my early school days, to the effect that the simplest way of doing things is usually the last to be discovered or made use of. So, at last, after all the various investigators in dental prosthesis have practically exhausted all sources in hunting for the truth, Hall brings forth for the profession a system of prosthetic dentistry extremely simple and comprehensive, and yet practical and scientific.

My object this evening is to prove to you that much of the technique given to the profession in past years, and considered absolutely necessary by many of the investigators for the successful construction of full upper and lower dentures, is to a large extent unnecessary.

It is now sixty years or more since Dr. Bonwill through an exhaustive study of several thousand skulls discovered that a line drawn from the center of one condyle to the center of the other measures approximately four inches, and a line drawn from this same center of the condyle on each side to the median line at the point where the inferior central incisors touch at their incisal edges is also approximately four inches. It is

true, however, that these measurements vary, but never more than half an inch. The average is an equilateral triangle, and this is the basis upon which Dr. Bonwill worked and constructed the first anatomical articulator.

All other investigators since Bonwill's time have used his discoveries as a basis for their work, but have centered their thoughts entirely on the movements of the condyles in the glenoid fossæ. The voluminous and complicated writings describing the importance of these movements include much exaggeration, are very confusing to the average practitioner, and have a tendency to retard rather than advance the general betterment of prosthesis.

But while the essayist believes that the greatly exaggerated importance of these scientific measurements has had a discouraging effect on the profession as a whole, yet great praise is due these investigators for their admirable work. It is a consequence of their efforts that Hall has been able to see the impracticability of much that has been presented, and has introduced into his method a wholesome amount of good common sense in addition to the scientific principles involved.

TECHNIQUE OF IMPRESSION TAKING.

The one great outstanding feature of Hall's method of impression taking is its accuracy. There must be an exact impression of the field examined—an actual negative copy of the parts taken in their natural, normal positions, without distortion or displacement of the soft tissues whatsoever. All the available surface is given the utmost consideration in order to give to the future denture the necessary stability, as well as a broad, flat seating surface, and to shut out all possible means of ingress of air. With these thoughts in mind, then, the closest possible attention is given to the examination of the mouth. The operator must form from his investigations a mental picture of the field to be utilized, and so firmly fix it in his mind that he will be able to recognize its accuracy immediately upon removal of the impression from the mouth.

EXAMINATION OF THE MOUTH.

For the sake of convenience in description of the examination we shall call the spaces usually found in the posterior part of the buccal cavity located between the cheek and the alveolar process, the right and left posterior buccal spaces. Beginning with the right posterior buccal space we estimate the height of the space from a level with the crest of the alveolar ridge to the arch forming the roof, and the width from the alveolar process to the buccal wall. Anteriorly from this space we note the downward inclination of the soft tissues to the region of the malar process of the maxilla. At this point we stop to determine the height of the muscular attachment on the alveolar ridge, and its flexibility. Passing from this point forward, we again note the upward inclination of the soft tissues in the region formerly occupied by the cuspid teeth. A gradual downward inclination of the soft tissues follows here to the labial frenum at the median line. Beginning again at the left posterior buccal space, the same order of procedure is followed to the median line on the opposite side of the maxilla. Next in order we examine the condition of the tissues overlying the alveolar ridge and hard palate. A careful digital examination is necessary to ascertain the density of the tissues, and to plan if necessary a possible means of relief.

In the examination of the lower jaw the same general plan is followed as in the upper. Every possible means is exerted to determine from the examination the accuracy of the impression. Like the upper, the lower also has two valuable spaces for retention generally overlooked in other methods of impression taking. These spaces, which are better known as the posterior lingual spaces and lie on both sides of the tongue, should be utilized to the fullest extent, since they form valuable aids in preventing horizontal movements of the denture.

INDIVIDUAL TRAYS.

In each case an individual tray is demanded. The S. S. White Co., following

the suggestion of Dr. Hall, manufactures an impression tray compound for this purpose. This compound possesses all the ideal qualifications necessary for tray construction, and is used exclusively in the technique of this method. It is black in color, softens quickly, and is not sticky except when immersed in very hot water. It sets rapidly, is not easily distorted, and can be cut easily with a sharp penknife.

MODELING COMPOUND IMPRESSIONS.

In performing the technique of taking the modeling compound impression an S. S. White metal tray is selected, a little larger than that ordinarily used in other methods of impression taking. The rim is cut and trimmed to follow the rise and fall of the soft tissues, generous relief being given the full extent of the rim to allow a substantial body to the periphery of the compound impression. The necessary amount of compound is then softened and evenly placed on the tray and the surface passed over a flame to give it a glaze. It is again immersed in hot water to prevent adhesion to the soft tissues, and is then placed in the mouth and is brought to position with a firm, even pressure, and allowed to remain a minute or so to prevent distortion upon removal.

All overhanging material is removed from the sides of the tray, to facilitate removal of the tray from the compound. This being done, one or two taps on the handle of the tray will usually cause a separation.

The essayist wishes to emphasize the importance of the compound impression. The technique must not be carried out in a careless, indifferent manner. This is the foundation upon which future success depends, and it must approximate in every detail the finished impression.

TRIMMING THE TRAY.

All the information gained in the course of examination of the mouth is now utilized in trimming the compound trays. In trimming the upper the same general outline given in detail under that

head (Examination of the Mouth) is followed in establishing the proper inclinations of the periphery from the median line to the posterior buccal spaces. The whole extent of the periphery is then reduced a little below the turn of the compound, and is given a slight bevel inclining away from the palatal side of the rim. Beginning on the labial surface it is trimmed back thin in the center to prevent pointing of the lip, and is gradually widened to the cuspid region to give that portion the desired fullness. It again narrows to the attachment of the buccal muscles. Posterior to this point it is given a little less width than estimated in the examination. The full extent of the buccal and labial surfaces is given a slant inclining away from the established width of the periphery to that portion of the tray representing the alveolar ridge, allowing space for the excess plaster which otherwise would create an unnatural fullness in the cheeks and lips.

We next direct our attention to the palatal surface and the posterior border, having in mind that the only pressure exerted in taking the impression is the natural pressure of the tongue. We trim and conform the palatal surface to its approximate shape, so that when placed in position the tray will have a firm, even pressure directed over the whole central portion of the base. The posterior border of the tray is trimmed to approximately the junction of the hard and soft palates, but in the essayist's opinion should always extend as far on to the soft tissues as can be comfortably borne by the patient. The prepared tray is then placed in the mouth and the spaces provided for the frenum and muscular attachments, and the periphery examined to determine their correctness. Finally, all overhanging points caused by undercuts are removed and liberal spaces allowed for soft, flabby ridges in the interior of the tray.

The same thoughtful consideration is given to trimming the lower, in order to obtain proper establishment of the periphery, contours, spaces for muscular attachments, and the lingual flanges, which should be well extended into the

posterior lingual spaces. Trim and contour the upper surface of the compound tray so that when the cheeks and lips are relaxed in the rest position they will assume their natural, normal location in the later plaster impression technique which is to follow.

PLASTER IMPRESSIONS.

In performing the technique of the upper impression, the rubber bowl is partly filled with water, a little salt being added to hasten the setting. The finest grade of French's plaster is sifted into the bowl until a little less than complete saturation occurs, and is quickly spatulated to give a smooth, even mix. The tray is then dropped into the bowl to give the palatal surface an even coating. It is now removed, a little plaster from the bowl is poured into the anterior portion of the tray, and the excess allowed to run off at the heels. The operator having assumed a position to the right side and slightly back of the patient, the tray is introduced into the mouth with the posterior border in advance and the cheeks pressed outward as the tray is advancing. The lip is then grasped in the center and brought forward, the tray leveled and with a gentle wave motion carried almost to position. The lip is now allowed to assume its normal rest position, and the whole surface of the tongue is brought in contact with the base of the tray to complete the pressure. The mouth is closed in the rest position and the impression allowed to remain until the plaster sets.

After a sufficient time has been allowed for the setting to occur, the impression is removed from the mouth and carefully examined. The black compound will indicate all points of undue pressure by its appearance through the plaster over the palatal surface and periphery. These points are relieved and the same order of procedure repeated. If on removal of the second impression the periphery shows a smooth, even roll, without any muscle strain, and the palatal portion an evenly distributed surface corresponding in every detail with the

mental picture formed from the original examination, we may feel assured that we have taken an accurate impression.

The technique of taking the lower impression is similar to that of the upper, with two exceptions, namely, the position of the operator in taking the impression and the method of introducing the tray. The patient is first directed to place the tip of the tongue in the anterior portion of the palate. The operator assumes a position directly in front of the patient and passes the tray under the tongue on the left side first, then brings it to position on the right, pressing the cheeks outward as he proceeds. The lip is grasped in the center and brought forward, and the tray allowed to settle of its own accord. The lip is now released, the two index fingers are placed in the region of the bicusps, and gentle pressure is exerted. The tongue then assumes its normal position, with the tip resting on the anterior portion of the tray. The mouth is closed and the impression allowed to remain until the plaster sets.

If the technique is properly carried out and the plaster mixed to the right consistence to cause a free, even flow, one will marvel at the beauty and accuracy of the impression.

ADVANTAGES OF PLASTER OVER OTHER METHODS OF IMPRESSION TAKING.

Hall's method of impression taking promises more uniform success with the lower jaw than does any other. It makes possible a stable, firmly seated denture, heretofore difficult of accomplishment even with the improved modeling compound technique. It demands careful attention, however; the operator must be exacting in every detail in order to be successful.

The underlying tissues are not subject to such great changes as occur under dentures constructed from impressions obtained by the so-called pressure method. It is absolutely impossible for one to determine with the fingers the amount of pressure to be exerted. Unnatural pressure is a detriment rather than a help;

it hastens the absorption of the hard tissues and causes an early loosening of the denture. This does not occur so rapidly in Hall's method, and accounts to a large extent for the continued stability of the denture. A slow, uniform absorption takes place and allows the denture to gradually and evenly follow its progress; for this reason relief is only necessary in extreme cases.

The physical aids of retention are exercised to their fullest extent. More surface is exposed to the force of atmospheric pressure, with a relative addition of adhesion and cohesion, without any corresponding increase in the weight of the denture.

It establishes more correctly the height of the periphery and provides more broad, flat seating surface for the base of the denture than any other method. It also eliminates all possible means of ingress of air and reduces the possibilities of soreness to a minimum.

Greater opportunities are offered in restoring the facial contours and exercising all other esthetic possibilities.

TECHNIQUE OF CAST AND BASE-PLATE CONSTRUCTION.

It is of the utmost importance in performing the following steps in the technique to be exacting in every detail. In order that we may eliminate every possible chance of destroying the accuracy of the impression, we must have a material that exhibits the least susceptibility to expansion and contraction in preparing the casts, and hard enough to prevent distortion under pressure. Spence's plaster possesses these properties and seems the ideal material for the purpose. The casts must be trimmed and prepared in such a way that we may obtain from them a base the exact duplicate of the finished denture to insure stability and accuracy in taking the bite.

FLOWING THE CASTS.

A portion of the compound is softened in hot water and rolled out flat on the bench. The impression is then placed in

the center of this flattened compound and encircled with a metal strip inserted in the compound allowing a space around the entire periphery a fourth to a half inch in width in order to provide on the finished cast a substantial margin. Spence's plaster mixed to a consistence equal to soft putty is carefully worked into the impression made by the alveolar ridge. It is then placed over the palatal portion and gently patted, larger pieces being added and jarred into position to eliminate bubbles and give the surface of the cast a smooth, even face. It is now set aside until it thoroughly hardens.

SEPARATING THE CASTS FROM THE PLASTER IMPRESSION.

After a sufficient time has been allowed for a complete hardening to occur, the metal strip is removed and the compound softened and carefully withdrawn from the cast. The plaster is broken away and the cast is ready for trimming. In trimming the cast a strong knife and coarse files are necessary, because of its hardness. The margins are reduced to a point an eighth of an inch or so above the turn of the periphery of the impression at its outer margin and follow the full extent of the outline. The object sought for in trimming is to preserve the whole surface of the periphery on the cast.

CONSTRUCTION OF THE BASE-PLATE.

The same method is followed in the construction of both upper and lower base-plates. A sheet of Alston base-plate material is placed over the cast and heated with the blowpipe until it softens and partly falls into position. It is then carefully adapted to the palatal surface and the alveolar ridge with the fingers, care being taken not to allow it to extend far enough over the ridge to include the undercuts. It is then trimmed with a hot spatula and removed from the cast, and the margins given a smooth finish with a file. It is again placed in position on the cast and a sheet of tinfoil is burnished over the entire

surface, allowing it to extend well beyond the outer margin of the peripheral groove. The full extent of the peripheral groove is then filled with rolls of soft beeswax, and a sheet of base-plate wax softened and uniformly adapted to the whole palatal portion. This is then trimmed and the base-plate is removed from the cast and given its final finish. The finished base-plate is again returned to the cast and tested for accuracy of fit, and corrected if necessary. A roll of soft wax is then fitted and molded to the alveolar ridge, following its form and approximating as near as possible the desired length of the bite rim in the mouth.

If care is exercised in performing the technique, this insures us a base-plate the exact duplicate of the base of the future denture, having a similar suction, and one that is not easily distorted and can be accurately fitted to the cast on completing the bite.

TECHNIQUE OF TAKING THE BITE.

Of all the various operations performed in the mouth, in the essayist's opinion none is so difficult of accomplishment as the establishment of the correct relation of the upper and lower jaws in taking the bite. The operator must have fixed in his mind the possible restorations, from knowledge gained in a close study of the face during this and previous engagements. He must be skilful technically and be possessed with a wonderful patience in order to determine the accuracy of the work as he proceeds.

In determining the length of the upper bite, the lip line with the muscles and mandible relaxed are used as an approximate guide only. It does not indicate truly the subsequent position of the teeth. In this position the lips are extended to their full length, and if accepted as a point of location would make the teeth entirely too long. It requires some effort on the part of the muscles following relaxation to bring the mandible to a position of occlusion without causing a contraction of the muscles and a slight compression of the lips. This position would indicate more accurately the bite,

and careful judgment must be exercised by the operator to recognize this distinction, which is so necessary in esthetics and efficiency in the finished denture.

In determining the length of the lower bite the lip line is again used only as a guide. The bite is trimmed below the level of the lip to a point representing the desired length of the underbite. If it were allowed to remain on a level with the lip and an attempt made to establish an underbite, the teeth would stand above the lip the distance corresponding in height to the depth of the established underbite. You will readily observe the fallacy of the accepted rule governing this point, namely, to trim the bite to approximate the line of the lips.

No attention is given to any predetermined method of establishing the plane of occlusion. The posterior occluding surfaces of the bite plates are trimmed and fitted to accommodate the case in hand, striving only to keep the surfaces uniform and to equalize as nearly as possible the distance between the jaws without disturbing the established bite length in the anterior portion.

The posterior occluding surfaces of the lower bite plate, that is, the surface extending from a point in the region of the cuspid teeth to the distal border, are purposely allowed to remain a little higher than the established bite length of the lip portion. This posterior portion is then heated deeply with a hot spatula, the bite plates are placed in position in the mouth, and the occluding surfaces are brought in contact with the jaws to complete the bite. The bite plates are then sealed together with a hot spatula, the median, high, and low lip lines indicated, and the bite removed and mounted on the articulator.

Many tricks and methods have been presented as aids in establishing the correct location of the lower jaw, such as turning the tip of the tongue back into the posterior part of the buccal cavity, swallowing, etc.; the final test, however, depends entirely upon the operator's knowledge of individual facial expression. By this means alone must he determine the accuracy of the bite.

USE OF THE ARTICULATOR.

The Hall articulator is something entirely new and is a real marvel in precision of adaptability to varying conditions in the human jaw. In its construction the attempt has been made to utilize every known law of science applicable, and the absolute exactness with which the normal movements and occlusion of any jaw can be copied is something that hitherto has been impossible of certain attainment. The troublesome face-bow adjustments of other systems—not mentioning time lost in such adjustment and possible inaccuracies of measurements in the end—are wholly eliminated. In other words, the Hall articulator combines accuracy with simplicity, a knowledge and application of strictly proper technique giving absolute assurance of success.

Any further description of the geometrical and mechanical principles upon which the articulator is constructed would be an imposition on the valuable time of the busy practitioner. He is concerned in the service it will render in a practical way rather than in a detailed description of its development. It possesses several particular advantages, however, which the essayist believes will be of special interest to the profession as a whole—namely:

A rotary movement which resembles more closely the movements of the lower jaw than in any other articulator. This movement because of the point of control permits a graceful, free swing not permitted by other articulators. It would require a very exacting and complicated apparatus to produce these movements with the point of control at the base of the triangle, or, practically speaking, in or near the condyles; but these movements can be produced by a very simple apparatus when the point of control is at the apex of the triangle as Hall has arranged it.

Another advantage is the forty-five-degree-angle guide plane located anteriorly to the apex of the triangle which establishes the articulating and occluding surfaces of the teeth, and which subsequently guides and directs the movements of the jaw during the process of mastication.

The next advantage is a removable bite jig which establishes the bite at an average distance from the base of the triangle or centers of the condyles, and eliminates entirely the use of the face-bow. The distance is based on the measurements of Bonwill's equilateral triangle.

Another great advantage is that the articulator may be set so as to permit only the opening and closing movement. This, along with the supporting pin at the apex of the triangle, greatly facilitates the arrangement of the teeth and eliminates much annoyance in retaining the line of occlusion as the work proceeds.

TOOTH ARRANGEMENT.

So much depends upon the proper arrangement of the teeth in the restoration of the lost masticating surfaces and the establishment of the natural appearance of the dentures, that it is absolutely necessary for the operator to have a full appreciation of the position and inclination which each tooth shall bear to the median line; or, in other words, he must have a definite reason for the position of every tooth and know exactly what the position means. The teeth are arranged with two definite purposes in view, *i.e.* appearance and mastication, and should be made to accomplish both purposes as fully as possible.

Many methods of manipulation in arranging the teeth have been presented, all of which have a reasonable degree of merit and will greatly aid in the procedure if used as a guide. Any set rule, however, governing a definite order of procedure in setting the teeth may be disregarded entirely. The results are the same, no matter where you begin.

Another feature which may be eliminated is any attempt to establish, by trimming and contouring the bite plates, the subsequent positions of the teeth. It is an absolute impossibility to determine in this manner what the arrangement shall be. This is determined entirely by the conditions to be met; it would be necessary in many cases to greatly modify or discard entirely any predetermined plan or arrangement on the bite for this purpose.

Following the arrangement of the teeth, the trial plates are removed from the casts and the wax given the final finish. This is possible only with bases made to accurately fit the casts and rigid enough to prevent distortion on removal. No other method offers the same advantage in estimating the palatal thickness and other esthetic requisites.

VULCANIZATION.

The technique under this head is not by any means so unimportant as generally considered by many practitioners. In fact it is the most important of all, and requires the closest possible attention to detail in investing, packing, and vulcanizing to retain as nearly as possible the true form of the finished denture. It would be folly indeed, after the performance of such a careful and exacting technique as has been described, to turn this part of the work over to incompetent and indifferent mechanics. The operator, to be successful, must perform the technique himself, or have a competent assistant working under his direction.

TAKING THE CORRECTIVE BITE.

The finished dentures are placed in the mouth and closely examined in order to determine the accuracy of the proposed corrective bite. The lower is then removed and a thickness of base-plate wax is adapted to the occlusal and incisal surfaces of the teeth and attached with a hot spatula. The waxed surfaces are now slightly softened and the dentures again returned to the mouth, the patient being directed to bring the occluding surfaces of the upper teeth in contact with the wax on the lower until the first indication of resistance is felt. The dentures are now removed from the mouth, firmly waxed together, and mounted in the established position, using the same order of technique as in mounting the original bite. After having removed the jig and wax from between the teeth, loosen the set-screw controlling the movement, and the teeth are ready for grinding.

GRINDING THE TEETH.

Cover the occluding surfaces of the lower teeth with a generous coating of carborundum and glycerin, and cause the articulator to perform the necessary movements by grasping the pin in the center and allowing its point to follow the established path of the forty-five-degree-angle guide plane. Continue the movements until fully satisfied that the articulating and occluding surfaces of the teeth have been properly ground to accommodate all the varying positions that the jaws may assume.

After having established the control planes on the surfaces of the teeth it is of the utmost importance to have the patient fully realize their purpose and use; and in order to obtain the full benefit of the arrangement in the mouth, a practical demonstration of the established movement is made with the articulator and the patient directed to imitate it as nearly as possible with the jaw.

The theory of having the forty-five-degree-angle plane guide to direct the movements of the jaw is contrary to all other teaching, and in the essayist's opinion will be the basis upon which the future success of prosthesis will depend. It simplifies the procedure, is more easily understood, and will be responsible in a large measure for a more rapid advancement in the prosthodontic art.

CONCLUSION.

By a close study of the carefully planned order of technique that has been presented, it will be readily observed that the successful construction of full upper and lower dentures does not depend upon exacting and complicated measurements or any particular make or type of articulator, but upon the patience, skill, and common sense of the operator working with an apparatus which approximates the movements of the jaw to aid him.

It has been the aim of the author in the presentation of this paper to simplify rather than complicate the procedure, in order to stimulate, if possible, a greater interest in the art and science of dental prosthesis.

The Past and Present of Operative Dentistry.

By B. HOLLY SMITH, D.D.S., Baltimore, Md.

(Address delivered at the fiftieth anniversary meeting of the Dental Society of the State of New York, Saratoga Springs, June 13-15, 1918.)

MR. PRESIDENT, LADIES AND GENTLEMEN:

I AM glad to come to New York, because of the fact that I have many friends here, and also the recollection of so many interesting occasions.

The interest that New York has always had in dentistry seems to me to be clearly shown by a casual survey of the early organization of our profession. In New York State there has always been a forward look. We had Dr. Carr tell us this morning something of the history of this organization up to date. (I told Dr. Carr I was mighty glad to hear him again in his old belligerent attitude.)

The organization of dentistry into the American Society of Dental Surgeons was accomplished here in New York, and its successor, the American Dental Association, which was the outgrowth of the American Dental Convention, was formed here also. I have a quotation here from Dr. Chapin A. Harris, showing the intimacy of the men who worked in Baltimore with the men in New York who had to do with the first institutions of teaching dentistry—the responsibility they felt for the advancement of dentistry, and the co-operation of the men of New York with these men in the organization of the first semi-national association known to dentistry.

As early as 1817, Dr. Hayden proposed the formation of a national dental society, and visits were made to Philadelphia, New York, and Boston to further this purpose; and yet it was not until 1840 that some fifteen or twenty men met in New York to organize the "American Society of Dental Surgeons." Dr. Hay-

den was elected the first president, Dr. Harris secretary. Three years later, this association, numbering one hundred and twenty-five members, met in Baltimore, and Dr. Harris in his address said:

In all great movements, either in religion, politics, science, or benevolence, the American character and the popular genius of all our institutions immediately direct us to lay hold on the great principle of voluntary association, as an agent of stronger moral power than any known in the country, to effect any desirable good. We have no wealthy and powerful privileged orders to command any given amelioration or improvement, and hence we combine the power of popular number and bring it to bear upon the objects we desire to accomplish. This national peculiarity accounts for the numerous benevolent and scientific associations found in the United States, before the moral power of which, vice, ignorance, empiricism, bigotry, oppression, and long-established habits and modes of thinking are fleeing away like mists of the morning before the rising sun. This will furnish the reason why America can boast of the first society of dental surgeons ever associated together in the world; and if this association shall produce results in any manner comparable to those produced by other American associations, now the wonder and praise of the world, the character of an American dental surgeon will stand as high on the archives of science as do the names of Washington, Franklin, Hancock, Henry, and Jefferson on the roll of freedom, or Mills, Judson, Perkins, and Hill in the annals of American missionary benevolence.

The American Society of Dental Surgeons was succeeded by the American Dental Convention, a body without constitution or by-laws—a simple meeting or

conference. This organization was of short duration, and was itself succeeded by the American Dental Association, which held its first meeting at Niagara Falls in 1859. This was from the first a delegate body and had a successful and continuous existence until merged with the Southern Dental Association into what we now proudly recognize as the National Dental Association.

GOLD FILLINGS.

A short time since I purchased a book, written in the City of Brotherly Love, which said, in the 43 pages devoted to the "stopping" process, that the hammered gold filling was ridiculous and obsolete. That was all that was said about gold fillings. It is interesting to know that in the time of Chapin A. Harris, whom I quoted in the early part of this address, dentists beat out their gold from the coin of the realm, and made fillings many of which are still in the places they were meant to fill. Those operators, of course, were few.

I do not believe Robert Arthur ever discovered cohesion. I think anybody who ever handled gold or gold foil must have discovered its cohesion and done everything they could to subdue that quality. Robert Arthur, however, got the credit for it, because he wrote a treatise on it, and thus opened a field that had not yet been occupied. Varney, Bonwill, Webb, and many other splendid operators later demonstrated the possibilities of cohesive gold.

It has been some time since the rubber dam and the electric mallet were considered of much importance, but for a long period they were the sheet anchor of the dentist. I do not know that I have a right to say this, but it seems to me a sort of disintegration of moral and ethical character to be swept off our feet because something new comes up:

Be not the first by whom the new is tried,
Nor yet the last to lay the old aside.

Do you remember J. Foster Flagg and the time the journals were so full of what was called the "new departure"? He

said he would never put in another gold filling as long as he lived, and an army of men said they would not either.

I do not believe you think the hammered gold filling is obsolete even yet, but there are many men in dentistry who would be glad to have an excuse not to hammer fillings, because they never did it properly.

I would like to make a plea for a partial return to the use of gold in filling teeth. The "new departure" only gave accentuation to a slovenly kind of work—for men who did a kind of crazy-quilt work. The dentist, I have always contended, is responsible to his patient and the profession for the well-being of the patient and for the esthetic effect of his work.

The non-cohesive gold filling had and still has its place in dentistry. I know Ottolengui never knew how to use it, because I have read his book; and naturally he did not find out its possibilities as I did. I believe every man should be armed with a variety of weapons, and be able to use just the one best suited to each case. I have heard men who were in practice twenty-five or thirty years say: "Well, I'm going home to try some of this non-cohesive gold." Now, I do not advocate it always, but there are times and places where it can be used effectively to the relief of the patient, and a cumbersome operation avoided. In my opinion it still has a place which cannot be taken by the inlay or any other material or procedure.

Think of what instruments have been invented, what splendid methods and technique developed, by the skilful use of cohesive gold. Are we to do without it entirely?

There are three factors that should influence a man in the selection of material for stoppings. First, he must have some consideration for suffering caused the patient. I felt very resentful toward this man [Dr. Stillman], who said everybody was against the dentist and children dreaded him. Why, children come to my office to play with the instruments I have in the office—and incidentally to have some dentistry done. It is not true, as

Judge McKelvie said this morning, that it takes as much force to drag a ten-year-old boy to the dentist as it does to take a drunken sailor to the lockup. I do not think any of us like steel on our teeth; it is a human and natural aversion; but dentistry is practiced today practically without pain. Secondly, there is the factor of the time required to do the work; and thirdly, that of the esthetic appearance in the mouth.

I have always thought the dentist must not only be a practitioner, but a teacher; but, God save the mark! I do not think the dental depot man has any business to teach the dentist what material he should use, and how he should use it. If he knows better how to use it, it is of course well for him to show us; but I think many men have been started on the wrong course in this way. I remember the man who came into our offices crying "Archite! Archite!" It ought to be written on his grave! There is a story of a certain man who would go out with his friends, partaking of everything they had to offer, but never spending any money himself. He disappeared, and someone asked: "Where is Jim?" They learned that he had died, and went out to the graveyard. There was Jim, six feet under, and over him was a little tablet: "This one is on me."

We had the same thing with artificial enamel. Those things were taken up because a drowning man clutches at a straw. Many men, because of their inability to use a certain excellent material, will grasp at any substitute. The artificial enamel was a godsend to such a man and his patients, and he was glad to bolster it up with anything the dealer might say. It was a failure in the most favorable sites, and many times poor discretion made it worse.

After all, it is not the material that determines the value of the filling, but it is the dentist who uses it. There is the man who sends the propaganda through his patients into the ears of your patients and mine: "Dr. So-and-so has a material that represents the tooth structure exactly, it does not hurt to have it put in, and it can be easily adapted to pre-

serving the teeth." That was poured into the ear of that person by the agent of some dental dealer, and that preaching has been to our students and to our young practitioners a great detriment, and we should guard against it. I give the dealer credit for many things. He has a large share in the usefulness of dentistry. He does it because he wants to make money out of what he produces, and he is entitled to do so if he produces the right thing.

Then there is the man who tells you about "silicious cement." He sets his inlays with "silicious cement." I would expect them to fall out unless they were well seated.

All honor to Dr. Black in his work for correct cavity preparation; we honor him wherever his name is mentioned. But Dr. Black was the leader of a camp, and many of his followers went under. Unquestionably a great amount of benefit has been derived from the proper preparation of cavities, and Dr. Conzett, who is one of the exponents of this, came to Baltimore last week, and gave us his ideas on the beveling of the cavo-line, which is of course very desirable for inlays. I said, "You come here to talk on operative dentistry, and you talk on gold inlays, and that makes me mad. Have you given up making gold fillings?" He said, "No, but that seems to be the most popular way to do it." I would not have my boy as a dental student be without the technique which he develops from the manipulation of varied forms of fillings, for anything in the world. He can train a girl in a few weeks to cast his inlays, and he can do his preparation of the cavities in his office in a little while. Dentistry is getting to be "easy," and I do not think we should consent to it. It is a slacking down, and a warping of the moral character of the operator, to say he is willing to give up that which we know has been so good, and go off into this new camp.

I know I have only touched a few phases of this subject, and the other gentlemen will bring out more interesting data than I have. I did not say anything about the combination of gold with other

materials. We have seen that at the clinics, combinations with cement and even with amalgam, the Morgan-Hastings gold, the Steurer's gold, and the other plastic forms which were a contribution to making gold filling easy.

There are few things I have ever seen for which I had a greater feeling of admiration than a certain mouth I saw—a patient of the late Dr. Perry's. There were no inlays. The mouth was clean, and it looked as fresh and sweet as a mountain spring. The saliva was free from any taint; of course it was a healthy subject, but the mouth was beautiful because of the splendid care of Dr. Perry. Could anyone persuade me that there could have been any error in the use of the materials Dr. Perry resorted to in the treatment of that mouth, and all the other mouths that came under his care? Of course, we can count the distinguished operators on our fingers, but that should not deter us from trying to imitate them. There are hundreds of men who have never come to the front in the conservation of tooth structure, and I suppose it is natural that they should be hunting some easy road to success, but let us not give up all that training which made the American dentist so peculiarly deft and skilful in the use of his fingers.

I used to fight with old Dr. Bonwill

about his patents. He spent almost a whole night with me arguing about it—it was somewhere in Kentucky—and the burden of his argument was that the things he had done that were really valuable he had given to the profession, one being bibulous paper, with which to pack amalgam. I have seen some of the plus amalgam fillings of Bonwill that were the envy of my life. They had been well made, and were lasting. These combinations of other materials with gold are still of value, and there is no reason why they should not be used.

I have wondered how it was that sometimes I saw, in the silicate cement I used, that brown line. I have seen silicate cements put in little tubes, dropped in water and then shaken up; it was evident there was a contraction. Dr. Head says these are indestructible and they stand wear. They will not stand wear when exposed to occlusal stress, and they are not satisfactory to build up angles. I have resorted to these silicate cements in facings, instead of showing the gold, but the man who says it should be substituted for more durable materials, I think, is wrong.

405 N. CHARLES ST.

[See also *Discussion*, as reported under "Proceedings of Societies," this issue.]

Topics of the Day: Curetting, Ionization, Pulp Testing.

By C. EDMUND KELLS, D.D.S., New Orleans, La.

The Curet.

THE word curet is frequently met with in the literature of the day, or rather has been frequently met with in comparatively recent magazine articles, and yet it is not to be found mentioned in many of the standard textbooks that are now in use.

HISTORY.

In the early days of the writer's practice, the amputation of root-ends, *when indicated*, was advocated by the most advanced operators. As there were no X-rays in those days, the "when indicated" was largely a matter of guesswork. When an abscess could not be cured, the supposition was that the root-end was roughened and therefore the abscess could not heal, and the sinus would not close.

The operative procedure then was to drill with the engine and a round bur through the gum tissue and alveolus—taking them just as found and without any preparatory treatment—and when the root-end was struck (?) to round it off nicely with the bur, and at the same time curet the abscess tract.

One can well imagine that the successful apicoectomist in those days was blessed with a vivid imagination, although, in this connection, one can safely say he did not differ greatly from a lot of our modern operators when vivid imaginations are taken into consideration. Be that as it may, the writer, having always been afflicted with an absence of imagination when it came to observing results, gave up curetting after a few naturally unsatisfactory attempts made in this manner.

THE SURGICAL CURET.

Within the past few years curetting has been revived, but this time the operator, evidently realizing that the engine bur was unfitted for the purpose, turned to the regular catalogued curets found in surgical supply houses, as there was nothing in that line in the dental depots at the time, and these are the curets that are used by all of the operators of the day, or at least by all operators who write or clinic upon the subject.

It so happens that for very many years replanting has been the writer's last resort for the cure of otherwise incurable abscesses, and many such abscesses have been cured without any curetting of the sockets. This proves conclusively that in every one of those cases at least, curetting was not necessary. Notwithstanding these results, upon a careful consideration of the subject it was realized that the immediate removal of the abscess sac from the socket (when it did not come away with the root when extracted) by means of a curet was undoubtedly a better procedure than leaving it there to be removed by the slow process of nature.

Immediately upon reaching these conclusions, the search for suitable curets naturally followed. The surgical curets of the day were found to be all built upon the same plan; they were of different sizes, some with curved shanks and some with straight, some being rights and some lefts.

While the general style of the instrument varied more or less, the curet proper, that is, the cutting end of the instrument, is practically of only one shape. It cannot be called spoon-shaped nor yet cup-shaped; it has rather a dis-

tinctive shape of its own, and this very shape is the *raison d'être* of this paper, for in the writer's mind this is about the most unsatisfactory, the most inefficient shape imaginable for dental work. It undoubtedly was primarily conceived by some surgeon for some surgical work, and probably was very well adapted to the work in question, but this did not necessarily fit it to dental work.

possible. This portion can only be touched by the oval part of the curet, and not by its cutting edge.

It may be possible, of course, that the writer is altogether wrong, that these surgical curets are especially well adapted to dental work, and that the reason he could not satisfactorily use them was due entirely to his own fault, and not to any defect in the instrument.

FIG. 1.

THE TEST.

It is only necessary for a careful operator to take an old skull, remove some of the teeth therefrom so that the sockets shall be perfectly natural, and then carefully go through the motions of curetting these sockets with the curet to be found upon the market. It is firmly believed that the more careful and more thorough the operator, the less would he be satisfied that he had thoroughly curetted the sockets in question.

Undoubtedly these instruments remove a good portion of what it is desired to remove, but their very shape precludes the walls of the socket from being well scraped all over, and as for reaching the bottom of the socket, that is simply im-

A NEW CURET.

Be that as it may, he certainly could not do the work to his own satisfaction, and so an entirely different curet was devised, with which he is well convinced that every part of any socket or abscess tract can be reached and thoroughly scraped.

In these days, when many of our instrument-makers appear to have been drafted into other lines, one must rely to a great extent upon himself for anything out of the ordinary. Fortunately, in this instance, a lot of standard files were in stock from which some of the curets in question could readily be made. In the illustration Fig. 1 an original file and the new curets are shown; that the

curets made from the files are not finished and nicked does not interfere with the results obtained.

The straight instrument is suited to accessible sockets only. In order to overcome the natural objections to right and left curets for sockets inaccessible to the straight instrument, the right-angle instrument, as shown, was devised.

THE ADJUSTABLE CURET.

This consists of an ordinary S. S. White porte-polisher in the end of which is secured a short curet. It is operated as follows:

A curet of the desired size is placed in the handle so as to first curet, we will say, the mesial wall, and that portion of the wall then coming within reach is thoroughly scraped. When this surface is satisfactorily scraped, the curet is removed from the socket and rotated slightly in the handle (there being a small hole drilled through the upper end of the curet so that it can be rotated by means of a point), say buccally, and the buccal portion of the wall, then coming within reach, is scraped. This is repeated—the scraping of the accessible part of the wall—and then the rotating of the curet in the handle until every vestige of the socket has been thoroughly curetted. The shape of the instrument is such that the bottom of the socket can be as well scraped as its sides.

Naturally, the sharper the curet the better it is adapted to the work. One of the advantages of this instrument is the ease with which it can be sharpened, as it is "hollow ground" on the order of a razor. Its sharpening reduces its size so that only the larger size will ever need replacing, the smaller sizes *coming along* all the time.

CONCLUSIONS.

The writer knows very well that every time *he* undertook to curet a socket with the original curet, there was a world of "camouflage" about the operation, which was very unsatisfactory to say the least, and it certainly was a relief to his mind

when he began to work with these new curets, from which moment the camouflage was eliminated.

Ionization.

Some twenty-five or thirty years ago, while attending a meeting of the old American Dental Association in Niagara Falls, the writer was persuaded to take up the use of ionization—then called cataphoresis—by a most enthusiastic dentist, who gave the most glowing accounts of its wonderful possibilities. Immediately upon his return home the cataphoresis apparatus was installed, and time and time again were abscesses "treated" in this manner, without any results whatsoever as far as the writer could see.

To be enthusiastic is a wonderful and in fact a very necessary asset, but enthusiasm should be based upon practical and not imaginary results obtained. With absolutely nothing but negative results, ionization, masquerading under the name of cataphoresis, was finally given up in despair.

THE OBJECTION TO IONIZATION.

Theoretically, ionization might be all right, and undoubtedly it is all right with those who use it successfully, or rather satisfactorily, for bear in mind there is a world of difference in the meaning of the two words. Ionization is too intangible for the writer. There is nothing definite nor positive about it. Some experimenters have proved it possible to accomplish certain definite results with it, while other experimenters of equal standing are just as firmly convinced in their views that these results never were accomplished.

The object of the procedure is to destroy the organisms beyond the end of the root when they are present. While the writer apparently cannot accomplish this by means of ionization, he certainly can do so in most cases, if not all, by the application of phenol under pressure. So many cases have yielded to this treat-

ment that long ago it became routine procedure in the treatment of putrescent pulps. As the details of this process have already been published* they will not be repeated here.

A PRACTICAL DEMONSTRATION.

The writer belongs to that large class of practical men who believe that it is easier to do good dental work on a skull at the laboratory bench than it is to accomplish equal results for an obstreperous patient in the chair. Consequently, what he can do in the mouth he certainly can do outside of it.

FIG. 2.

In Fig. 2 is shown a photograph of a lower jaw with a first and a second bicuspid as the experimental teeth. The bone around the apices of the two bicuspids was carefully burred away, making two independent and non-communicating abscess cavities. The porous surfaces thus left exposed were coated with wax to render them impervious. The cavities were filled with cotton thoroughly infected with organisms, then sealed over with sealing-wax, and thus first-class abscesses were simulated.

The teeth were then treated by this pressure method. The second bicuspid having been opened through into the ab-

cess, a successful result was expected. With the first bicuspid it was different. It was not possible to open the canal through into the abscess, and consequently a failure was expected. After these treatments (one sitting) the case was returned to Dr. Foster M. Johns, who had infected the cotton, with the report that the first bicuspid's abscess would not be sterile, while the abscess under the second bicuspid should be sterile, and his tests proved the correctness of this assumption, for every vestige of infection was gone under the tooth which was supposed to be satisfactorily treated, while the abscess under the first bicuspid was still alive with organisms.

Undoubtedly there may be many men who will say there is nothing in this experiment, but it proves to the writer at least that he accomplished what he set out to do. When he follows the same routine in the mouth, he usually, though not always, obtains the same result. Results being all that count with him, he is satisfied.

CONCLUSION.

Ionization fulfils no purpose in this office.

Pulp Testing.

Some ten years ago or more, Dr. Prinz brought out a galvanic pulp tester, by means of which it was supposed to be possible to determine absolutely whether or not the pulp of a tooth was dead or alive, a much-needed device. Theoretically it certainly was fine, but in the writer's hands its use was not satisfactory, and so its employment was soon discontinued.

Quite recently, manufacturers have placed upon the market pulp testers to be operated upon the 110-volt current. Last fall, while visiting a friend in the East, one of these testers was shown to me by its enthusiastic owner, and after his very interesting dissertation upon it and its invaluable qualities, naturally a pulp tester was ordered.

Shortly after its receipt, a splendid opportunity for its use arose. A patient

* See *Dental Items of Interest*, August 1917, vol. xxxix, p. 561.

presented with every indication of an inflamed pulp. The dam was applied, the pulp tester connected up, and it gave a positive and unmistakable reaction, thus showing the pulp to be alive. A large inlay was then removed from the tooth, and a sharp bur was carefully driven right down into a putrescent pulp! A skiagraph was then taken, and typical light areas were shown about the root-ends.

The "enthusiastic friend" was given these details, whereupon he wrote as follows: "At a clinic all hands agreed that a certain tooth *appeared* to be devitalized. The pulp tester was applied, and it gave positive and unmistakable signs that the pulp was vital. A skiagraph was then taken, which showed that the roots were filled!"

Dr. Hermann Prinz now says that under certain conditions dead teeth can be *proved vital* by the electrical test.

In discussing this question with Dr. Thoma he said that it is possible for the nerve fibers in a pulp to be still vital shortly after the pulp has become putrescent.

Quite recently the writer was in conversation with one of the "stars" who tours the country, holding classes as he goes, along these lines. When it came to pulp testing, he had listed three

methods: (1) Electrical. (2) Thermal. (3) Actual penetration.

He was asked, "Is the electrical test always positive?" He answered, "No." To the query, "Is the thermal test always positive?" he replied, "No." To the question, "Then in a final analysis the *only real way*, in this the year 1918, to tell whether or not a pulp is dead or alive is to drill into it?" the answer was "Yes."

And there you are!

Now, readers, as before stated, we are first, last, and all the time striving for results, and in this instance, not getting results, why go through all the motions of an electrical test if, after we have made the test, we are not sure that its result is positive?

At the beginning of the test we are in doubt. We know not whether the pulp is dying, dead, or alive. We make the test; it shows that the pulp is dead, and still we are not sure of it. Or it may show that the pulp is alive, and then we are not sure of that either, so what's the use? Such tests are not in our line, and they are no longer made.

CONCLUSION.

An up-to-date pulp tester *for sale!*

1237 MAISON BLANCHE.

Report of the Committee on Practice—Dental Society of the State of New York.

By PAUL R. STILLMAN, D.D.S., New York, N. Y.,

CHAIRMAN OF THE COMMITTEE.

(Read before the fiftieth anniversary meeting of the Dental Society of the State of New York, Saratoga Springs, June 13, 1918.)

IN reviewing the subject of practice, your committee is unable to report any epoch-making achievement or conspicuous advancement in dental science during the past year. There has been, however, a remarkable excellence in the current literature in dental science. This would seem to indicate a growing culture in professional work in marked contrast to that of a decade ago. The interest in postgraduate study is vigorous and widespread, and this interest extends practically to every department of dentistry.

Indicative of the professional interest shown in the problem of periodontal and periapical infections, is the fact that both the First and the Second districts of this society have given their entire attention to these subjects in the scientific programs of their meetings.

The pendulum of professional interest swings to extremes. Time was, and it seems but a short interval since, when the subjects of pyorrhea and the management of root-canal fillings brought but only a meager squad of regular attendants when these subjects were announced for discussion at society meetings. It was then the technique that was of particular interest. At the October meeting of the First District Dental Society not less than three hundred intensely interested members sat for two and one-half hours and listened while Dr. Frederick B. Noyes of Chicago discussed his slides, dozens of which were exhibited, showing the intimate forms

and relations of the tissue cells of the teeth and their investing structures.

ROOT-CANAL TREATMENT.

Until very recently dentistry has failed to take cognizance of the importance of applied histology and pathology as revealed by photomicrography. The sadly meager preparation in these fundamentals which most of us received while preparing for our D.D.S. degree left us quite unprepared as to the basic principles underlying the demands of our present practice. So long as we confined ourselves to the filling of cavities of the teeth or the making of two-piece gold crowns, we were well within the range of our capabilities; but when we undertook the treatment of septic root-canals of teeth which had lost their blood and lymph supply through infections of the pulp; when we treated these conditions empirically, vacillating from one recommended nostrum to another and in vain hoping for success, a degree of knowledge was required which the average practitioner did not possess.

In retrospection of the past twenty years it is difficult to conceive of a more dangerous and unsurgical procedure than the sealing up of root-canals which contained dead animal tissue. The periapical infections which followed this practice are so universally believed at this time to be the foci of metastatic disease that mention here would seem almost superfluous. It would be just to call at-

tention to the fact that during the period of darkness through which we passed there were a few enlightened men in our profession whose practice and teaching will stand out prominently through posterity whenever this subject is discussed. These pioneers understood the pathologic significance of these infections even when their sequelæ were yet to be revealed. They did not then know that periapical infection by streptococcus viridans was productive of arthritis deformans, arterio-sclerosis, rheumatism, and the numerous other lesions which recent researches have disclosed. What is remarkable and most extraordinary is the fact that the pulpless teeth the roots of which were filled by these men more than half a score of years ago, were at that time conscientiously cleaned of the entire pulp contents and the canals filled, yes, even to and sometimes through the apex and encapsulating it—and this during a period when our colleges were teaching a technique of filling root-canals with cotton wool and iodoform. All honor to these great men.

The indictment of the dental profession for the practice of surgical crime in the treatment of root-canals is a matter of history.

Calling forth much attention in dentistry, and a decided step in advance of the accepted theories in general surgery, is the application of the principle of ionic sterilization.

To sterilize an infected tissue while it is yet within the body is an epoch-making procedure. Well may Medicine extend her interest in the science of dentistry, for have we not taught her that teeth are the sources of infection in many diseases in which she had been satisfied to treat the symptoms, for the reason that she did not know and would not believe there was anything else to treat? Modern dentistry has accomplished this, and offers abundant and convincing proof in hundreds of radiographic records of cases reported as evidence that a true sterilization of infectious periapical areas has been accomplished and bone regeneration excited by means of ionic medication.

Periapical infection from the surgical standpoint demands root resection and drainage, and while this is at times necessary, sterilization without drainage is an accomplished fact.

CONDUCTION ANESTHESIA.

The recent achievements of dentistry in conduction anesthesia of the head by the blocking of the ganglia of the fifth nerve have been so marked that this method of producing anesthesia has been adopted by the medical specialist in throat surgery. The infiltration of an infected tonsil hypodermically, a quite unsurgical procedure, has been practiced extensively. It may now be abandoned for it is possible to anesthetize a tonsil by nerve-blocking, and to carefully dissect it out with complete absence of pain. Dentistry is teaching medicine some things which must have a profound influence on surgical practice. Not only must the dentist radiograph the teeth and alveolar processes for his own diagnosis, but the surgeon must also have this information for the diagnosis of all cases of obscure metastatic origin, the diagnosis being made by the dentist.

U. S. ARMY DENTAL CORPS.

The organizing of the U. S. Army Dental Corps as one of the constituent parts of the medical department of the army under the supervision of the Surgeon-general of the army comes as a happy consummation of the fond hopes of our profession. Dentists have long felt that dentistry is and long has been an integral part of medicine. While it has been taught in separate schools because of the technical procedures which require special teaching and clinical requirements, its curriculum has expanded and advanced along with that of medicine.

The fundamental sciences which collectively compose the study of medicine are duplicated in the dental schools. The preparation of students in the best institutions of dentistry in such sciences as anatomy, physiology, chemistry, histol-

ogy, and general pathology are not surpassed by accepted medical schools. The requirements for dental matriculation and graduation have been brought up to the present-day standards which have been set by similar medical schools.

These facts, however, seem not to be the poignant reason for the present recognition which has been for so many years withheld. It has come through a widespread acceptance of the relative importance of the rôle which mouth infections play in the etiology of systemic diseases. It has been through the results of dental as well as medical research that the present intimate relation of medicine and dentistry has been brought about. During the past five years the attention of the whole world has been incessantly called to the results of dental science in the treatment of oral infections and their sequelæ. Infections of the eye, ear, nose, and throat, infections of the heart muscles, the joints, the whole gastro-enterologic tract, etc., have been correctly attributed to foci which are legally and otherwise within the exclusive field of dentistry. Cases in private practice, many of which have never been reported but which are in their importance no less impressive, have centered the attention of the whole world upon the importance of oral health and its application in medical prophylaxis. Couple these facts with the reports from the European hospitals that wounds of the face and fractures of the jaws compose twenty per cent. of all injuries which are brought in, and many of these complicated and prejudiced by the presence of septic teeth; the prevalence of "trench mouth," which is doubtless a type of ulcerative gingivitis—Vincent's fusiform bacillus infection, an infection of the gingiva which is the most devastating of all oral infections—and we may appreciate the importance of the rôle which the U. S. army dental corps is expected to assume.

TREATMENT OF INJURIES OF THE JAWS.

During the past year there have been shown at various medical and dental

gatherings a large number and a great variety of lantern slides and even some motion pictures, detailing all sorts of jaw operations and methods of treating jaw cases. Slides have been exhibited which were made from photographs taken at the hospitals of the Central Powers as well as from those of the Allies. The notable and outstanding feature in connection with all these exhibits has been the marked contrast in the methods as well as the results obtained in cases where operation or treatment was supplemented by the use of orthodontic appliances, and those where other types were used. The orthodontic appliances as exhibited were very poorly selected, and their manner of adjustment indicated a lack of fine orthodontic technique which could not fail to impress an orthodontist with the crude management of these cases. In spite of this, the results in the cases which were treated by orthodontic methods were far superior to those in which any other method was employed.

The metal or vulcanite interdental splint or any other appliance which locks the jaws is dangerous to life, as well as being clumsy and unsanitary. The disadvantage of appliances of this type is practically illustrated by the case of nearly one hundred British soldiers who were being returned to England by a Channel boat. The men were all wearing in one form or another interdental splints. Seasickness, with its usual symptom of vomit, caused the death by strangulation of these wounded. This makes one inquire why the knowledge and skill of the specialists in orthodontia has not been mobilized by the medical corps of the army for the benefit of our own boys.

SPECIALIZATION IN DENTISTRY.

This is the era of the dental specialist. The ranks of general practice are being deserted daily. The busiest men in dentistry are quietly taking up special branches and delegating to associates those departments of general practice in which they recognize personal and professional weakness, or for which they

have an actual distaste. First it was exodontia. The extraction case was a nuisance in the office. The extraction specialist solicited this work, which was never profitable unless done in volume, and so all cases were thereafter referred to this specialist. Next it was orthodontia. Who has not heard the tales and seen the fearful and terrifying results of pre-Angle orthodontia—arches mutilated by the extraction of sound teeth? For at that time it was believed that the teeth were too large for the jaws. The general practitioner was glad to delegate this work to skilful hands when the necessity of normal occlusion was finally understood.

The specialist in prosthetic dentistry developed into a prosthodontist through his conspicuously superior skill. At first only those cases which had been classed as "probably impossible to fit" after an experience of several failures were referred to him. Previous to the perfecting of the anatomical articulator vulcanite dentures were the least profitable kind of practice. Vulcanizing was malodorous and plaster of Paris kept the office untidy. Crown and bridge work came in, and the vulcanizer was forced out of the laboratory.

The casting process of Taggart revolutionized both operative and prosthetic dentistry. In the last twenty years almost every method and principle of practice, except the cavity preparation of Black, has been abandoned for newer, more modern, and obviously better methods. The amalgam filling has burst its cocoon, and from that disgusting larva—the thumb-carved abortion of the late nineties—it has emerged into a beautiful butterfly, the carved, contoured, and burnished amalgam restoration of the present day.

The pyorrhea specialist has developed into a periodontist, choosing as an exclusive specialty the treatment of the several pathologic conditions which attack the investing tissues of the teeth.

There is also the radiodontist or dental roentgenologist. Soon there will be other specialties. Where will it all end? Is dentistry to disintegrate through this

process of division and subdivision? Twenty-five years ago there were simply operative and mechanical dentistry and we all specialized in *both*. Today the conscientious dentist must spread himself out very thin, or realize that he has fallen down and is being buried under an avalanche of practical results of research and modern methods due to scientific investigation.

There is an ancient adage which says, "One swallow does not make a summer." In the light of the advancement which has been made in the practice of dentistry during the past few years may we not paraphrase, and say, "One graduate does not make a dentist?" Are we to believe that this beloved profession of ours has outgrown the man, or that the sporadic development of specialists in dentistry over the length and breadth of this continent has sounded the death knell of the general practitioner? The Middle West and the Pacific Coast have two specialists (to the percentage of population) to one in the East. Specialization is in the very air.

Every dentist who is worthy of the name and who still possesses the vigor of his manhood is making every effort and straining every fiber in an effort to adopt into his daily practice the conspicuous improvements that are at intervals being introduced; meanwhile the avalanche of excellent material is continuously descending upon him.

What of the public—the laity who compose the vast *clientèle* of dentists? Do these millions like the new era? Do they approve of being sent to this office for one operation and to that one for another? They do not. They are demanding service of every conceivable dental sort from the specialist, and they are being inconsistently refused. An efficiency engineer has expressed himself as follows:

You specialists are making the greatest mistake of your professional history with your medieval methods of conducting your practices. You deny that their is competition, and yet you all compete. Are you more ethical than the banker or the engineer or the architect or the surgeon? You are not.

Certainly banking is a business and so is every professional occupation a business—when it is successful—and when it is not a business it is a business failure. This idea of being sent from one office to another, from one dentist to another, is absurd. Who would enjoy a banquet which served the soup in Washington Square and coffee on Washington Heights and the other courses all along the route? Did you ever hear of the Mayo brothers, the doctors of Rochester, Minn.? Are they ethical? Are they respected? Who is the president of the American Medical Association? Dr. Charles Mayo. Is he the best surgeon in the world? Probably not, but he and his brother are the most successful physicians in the world. They are serving the public better than any others in the world because they understand the modern idea of consolidation and co-operation. The trouble with you dentists is that you do not know the elements of economy nor the meaning of the word business. As a class you do not make one good investment of your savings in ten. You are notorious marks for the wild-cat-scheme promoter and the fake mine-stock salesman. If it takes six of you fellows to make one dentist, for God's sake consolidate and make one. Save the item of at least five office rents per year and distribute the sum among yourselves, and don't forget that you need a business associate to look after that department, for there isn't a single business man in your whole profession.

Can it be true that this is the opinion concerning dentistry which is held by others besides this efficiency enthusiast? Would it be possible, for instance, to group the four dentists in a village of, say 2500 population into a co-operative group with one common reception room and suite of offices, and to persuade the young teller of the local bank to become a business associate with an equal interest in the earnings with the other associates? Your committee does not presume to answer. It is possible to conduct a medical and surgical hospital wherever one can be supported. Why not a dental hospital?

This conversation is interpolated in this report to arouse discussion. It is submitted.

Those who have made the most conspicuous success of specialties have done so after some years which have been devoted to general practice. In other words,

they have evolved in the natural way. The special field in which their talents and their tastes have developed gradually crowded the other branches of work out of the daily routine. A short course of postgraduate instruction to clear up some of the less understood or the more perplexing phases of their work, or some instruction by the side of a preceptor who had developed further in the specialty, sufficed at best to convert the general practitioner into a full blown specialist.

Now we have seen emerge the schools for the making of the dental neophyte into a dental specialist. Young men fresh from college who are still without the important and broadening experience of several years of successful practice are entering these institutions. The next step is the mailing of the familiar announcement which informs all who may receive it: "Practice limited, etc. Office hours 10.30 to 2."

The entering into specialization signifies a frankly acknowledged ability in some chosen special branch. When an announcement is backed by real ability plus experience, the world is better for the change perhaps, but when a specialist is announced whose only excuse is a greedy desire to profit at the expense of the profession and public and a desire for larger fees and shorter hours, every man in the profession is at once personally injured.

The time was, and in this state it was less than forty years ago, when anyone could practice dentistry if he could make the public believe he could. Our society put a stop to this, and had passed a dental law which protected both the dentist and the public. The day is not far distant when the law will be called upon to protect the public from and which will define the specialist. This committee respectfully recommends to our president and to the Legislative Committee that an investigation be made into the abuses of pseudo-specialists, and that suitable laws be submitted to the State Legislature which will define the specialist and authorize and license only those who are competent.

There is another danger, and that is to the specialist. The past president of the National Dental Association, Dr. L. L. Barber, in his address last year, had this to say:

The danger of specialization is its narrowing influence. It is an extraordinary man who can continue upon a single objective without losing his sense of proportion. Brains, as farm lands, are enriched by diversification, and deteriorate when devoted too long to the same purpose. Efficient thinkers re-vitalize their minds with a variety of interests. Their intelligence remains symmetrical. When a subject especially appeals to you, beware lest you become so wrapped up in it that, like the silkworm, you shut yourself off from all the other wonderful things in view.

Nevertheless, specialization has its advantages and no man is so large that he can comprehend to the fullest all the phases of any profession. But let us not specialize until we become too narrow between the eyes, and our horizon not farther away than the end of our nose.

Like the proverbial fat man, no one really loves a specialist. The long-suffering public patronize them when they feel that they can afford to do so, yet they never love them as they have loved the family dentist. They recommend them to their friends with the same enthusiasm, however, as the small boy, just emerging from the side show where he has just seen the seven-legged horse or the two-headed calf, recommends the show to his friends.

The dean of the graduate department of an important university once called a specialist, "One who knew so much more about one thing than he knew about everything else, that he thought he knew more about it than anyone else did." To which someone has ventured to add that "There also is the variety of specialist who is inclined to think that if he gives any thought to any other subject, he will know more about it than anyone else knows."

Your committee presents you with the specialist already in your midst, and in the classic interrogation made famous by the late Richard Croker, asks "What are you going to do about it?" So commendable is the thirst for knowledge and

so desirable is its satisfaction that nobody should even dream of criticizing adversely the admirable ambition of those who act upon a stern determination to thoroughly prepare themselves to render service as one of our several recognized specialists. Those who have become recognized as specialists are doing all they can by means of special articles, lectures, private courses of instruction, etc., on the theories and practices of their several specialties, with a generous devotion and desire to help any brother practitioner in the achievement of a laudable ambition. Not every practitioner who enters upon a special course of postgraduate study does so for the express purpose of entering upon the practice of an exclusive specialty. Many enter these classes largely for the academic value and the broadening influence which special knowledge must necessarily have in the daily routine of office work. The broader the academic knowledge of dentistry in the field of the specialist, the greater becomes the difficulty for the man so educated to be satisfied to putter and plod along with methods and technique which he has previously employed, and which he has come to recognize as antiquated or obsolete. He recognizes his personal incapacity to excel or even compete with the superior skill of others who devote their whole professional life to work within definite, prescribed limits. He acknowledges to himself that all of us can no longer become successful specialists at once in every department of dentistry.

To possess the broad, academic knowledge which is expressed in a familiarity with the working principles of every department is an essential which all should possess. To be able to recognize and make correct diagnoses of conditions as they present, and to decide in the interest of the patient whether an operation and treatment should be personally undertaken or whether in conscience the work should be referred to another man of admitted superior experience and skill, is the province of every ethical postgraduate.

Take for instance the specialty of or-

thodontia. Not every dentist who has taken special postgraduate work in orthodontia feels free to accept each and every class of cases together with the responsibilities of general practice, and it is this type of man who generally becomes convinced that he must either refer all cases in this branch to a specialist or forsake the burden of general practice and devote his whole time to the study of this new science, which is recognized to be big enough to satisfy his ambitions. To be able to recognize malocclusion and to appreciate the imperative need for early treatment for those who are so afflicted does not demand a co-existing responsibility to personally treat these cases. To "tell time" one does not have to know much more about a watch or clock than that it needs periodical winding, and as a matter of fact, that is all anybody except the makers and repairers of watches and clocks do know about either. We

can contentedly and safely leave such knowledge to specialists, and of necessity we take this attitude in regard to orthodontia, and thus, to be consistent, with all of the other branches of specialized science practical knowledge of which we may by chance fail to possess. The real crime is that one often leaves the work to the incompetent or ignores the necessity for treatment altogether, thus allowing patients to develop into dental cripples by shirking a responsibility either through ignorance or greedy avarice. It is not that one is not a specialist and skilled in the technical details of an exclusive specialty, it is that he fails in his duty to his patient, a duty which carries a greater responsibility year by year as our science develops.

Physiological Age: The Relation of Dentition to Body Growth.

By **LESLIE SPIER**, New York, N. Y.,

AMERICAN MUSEUM OF NATURAL HISTORY, NEW YORK.

(Read before the Eastern Association of Graduates of the Angle School of Orthodontia, New York City, May 6, 1918.)

NO hard and fast line can be drawn between the pathological and the normal. We recognize morbid cases of the extreme type easily, but on the other hand we all admit that normal individuals exhibit a certain amount of variation among themselves. Just where we are to draw the line between those we choose to call normal variants and those we call pathological really varies with the point of view of the moment. The orthodontist today corrects condi-

tions which in our fathers' time were not considered sufficiently abnormal to warrant treatment. In other words, today we draw the line much closer to the normal.

When we reflect on this point we see that there can be no gap between the normal and the pathological; individuals grade by degrees from the normal to the extreme types. Now, this is the essential characteristic of all variable phenomena, and so inflexible is the rule that we find

that one simple type of expression fits any varying phenomenon. If we rank a company of soldiers according to stature, or arrange all the leaves of a tree by length, or whatever class of objects you choose, we always find that most of the individuals stand closest to the average, taller and shorter individuals are fewer in number, and extremely tall or extremely short individuals will hardly be found at all.

Curiously enough, if we toss a number of coins, say seven, the possible ways they can fall, counting only heads, are:

| Heads. | Frequency. |
|--------|------------|
| 0 | 1 |
| 1 | 7 |
| 2 | 21 |
| 3 | 35 |
| 4 | 35 |
| 5 | 21 |
| 6 | 7 |
| 7 | 1 |
| | <hr/> 128 |

That is, in 128 trials we may expect the seven coins to give no heads once, one head seven times, two heads twenty-one times, etc. We are accustomed to say that the tossing of the coins is governed only by "chance" and that the resulting record represents "accidental" frequencies. The mathematician tells us that "chance" represents merely a multiplicity of factors operating at the same time on a class of objects which are free to be affected by causes producing variation. He would expect to find in a company of 128 soldiers that there was only one individual of the shortest stature, seven next taller, twenty-one next, etc.; that is, in regard to stature or any other characteristic, they would vary freely according to the "law of chance." So, too, we find that the morphology and physiology of the normal type varies in exactly the same way to such an extent that we are constrained to call the extreme variants pathological cases.

The human body is a delicate mechanism and subjected to the vicissitudes accompanying the growing period, and

we may well expect accidental variations to be perpetuated in the adult form. Naturally the effect of these vicissitudes must be cumulative; diseases of infancy impair growth, later favorable nutrition may accelerate it, still later the child's growth may again be retarded by the development of morbid characters, and so on until the cumulative effect of these physiological disturbances is fixed in the adult form. The course of growth for a group of children may be conceptualized as similar to that of a group of balls rolling down a bowling alley. Let the balls be essentially identical, let them receive at the same instant the same initial impetus; now one meets an obstruction and lags, now another, then a third is accelerated by a smooth stretch, and so on; before long they have perceptibly scattered, and the longer the course they run the greater the degree of scattering will be. So a group of children show variations in the age at which they pass through particular physiological states; that is, as Professor Boas long ago explained, the variations in the period of development found in the group are due to accelerations and retardations of growth.

I have determined such variations in dental development of a group of 350 Porto Rican boys. The following figures give the average ages at which the deciduous teeth are shed and the variation in years of the occurrence of that process:*

* The mathematician has a convenient measure of the variation of a free variable in the "mean square variability," or simply the "variability." When he says that upper outer deciduous incisors are shed at 7.8 ± 1.6 years, he means that the average age was 7.8 years but that 34 per cent. of the boys shed the teeth between the ages of 7.8 and $(7.8 \pm 1.6) = 9.4$ and another 34 per cent. shed them between $(7.8 \pm 1.6) = 6.2$ and 7.8. The "variability," here 1.6, shows the degree of scattering of the bulk (68 per cent.) of the losses about the average. When the "variability" is small, then the mass stands close to the average; when it is large, the scattering is great.

TABLE I: LOSS OF THE DECIDUOUS TEETH.

| | Outer incisors. | Canines. | First molars. | Second molars. |
|-----------------|-----------------|---------------|---------------|----------------|
| Upper | 7.8 ± 1.6 | 9.5 ± 2.5 | 9.1 ± 1.9 | 10.3 ± 2.1 |
| Lower | | 8.4 ± 2.2 | 8.9 ± 2.2 | 9.2 ± 3.2 |

Similarly, the ages at which the permanent teeth are erupted and the tardations brought about by the earlier vicissitudes they have suffered. Since the stage of development of a variability are as follows:

TABLE II: ERUPTION OF THE PERMANENT TEETH.

| | Inner incisors. | Outer incisors. | Canines. | First bicuspid. | Second bicuspid. | Second molars. |
|-----------------|-----------------|-----------------|----------------|-----------------|------------------|----------------|
| Upper | | 8.5 ± 1.4 | 10.3 ± 2.2 | 9.2 ± 2.0 | 10.7 ± 2.0 | 12.1 ± 1.7 |
| Lower | 6.2 ± 1.5 | 7.0 ± 1.3 | 9.0 ± 2.3 | 9.9 ± 1.8 | 10.9 ± 2.0 | 11.4 ± 2.0 |

These periods of dental development are, of course, roughly true only for Porto Rican boys. We obtain other figures for girls, for other races, and for other social groups. For example, for Boston school children Channing and Wissler found the following values for the eruption of the upper permanent teeth:

child at any period depends on the previous acceleration or retardation of its growth, which must have affected the whole body in some measure, it follows that all measurements taken on that child must vary in the same direction from the average of the group; either all values must be increased beyond the aver-

TABLE III: BOSTON SCHOOL CHILDREN—ERUPTION OF UPPER PERMANENT TEETH.

| | Inner incisors. | Outer incisors. | Canines. | First bicuspid. | Second bicuspid. | Second molars. |
|-----------------|-----------------|-----------------|----------------|-----------------|------------------|----------------|
| Boys | 7.5 ± 1.4 | 9.5 ± 2.1 | 11.2 ± 1.4 | 9.4 ± 2.2 | 11.4 ± 2.9 | 13.2 ± 2.0 |
| Girls | 7.0 ± 1.6 | 8.9 ± 2.1 | 11.3 ± 1.0 | 9.5 ± 2.5 | 11.2 ± 2.9 | 12.8 ± 1.6 |

As these figures stand, the Porto Rican boys appear to erupt their teeth as much as a year in advance of the Boston boys. However, the meaning of this is obscure, since the same observers also found that a group of feeble-minded children erupted their canines and second molars a corresponding period in advance of these Boston boys. (See Table IV.)

These variations, which we find in the age at which children pass through the same physiological stage, must be regarded as due to accelerations and re-

age for its age by acceleration or all depressed by retardation. The interrelation

TABLE IV.

| | Boys. | Girls. |
|-------------------------|----------------|----------------|
| Canines | 10.7 ± 1.4 | 10.0 ± 1.7 |
| Second molars | 10.9 ± 1.9 | 11.8 ± 0.9 |

of these measurements, which are indices of physiological development, varies with

the rate of growth. After birth the rate of growth declines until it reaches a minimum, in girls, at about 8.2 years, then it increases very rapidly until a maximum is reached at 11.2 years (these figures are 10.3 and 13.2 for boys), after which it again declines until growth ceases.

Let us imagine our figurative bowling alley built on a series of inclines to represent these conditions; first an incline upward, then a sharp down stretch, then a slightly rising plane to the end. When the group of balls reaches the first break they have already scattered somewhat. Those that are accelerated reach the declivity first, they shoot ahead leaving the retarded ones behind, and the scattering of the whole group is thus greatly increased. Now the accelerated reach the foot of the ascent, their speed is checked, the retarded catch up with them and the scattering is markedly reduced.

Leaving aside for a moment the effect of this on the group considered as a whole, we see that for any individual the more rapid the rate of growth the greater is the effect of variation in period on all his measurements. A retarded child will fall farther behind his age-mates at this time and fall behind in his entire development. We find that this has the effect of increasing the correlation between all measurements during the period of rapid growth and conversely decreasing it during the decline of growth.

Since, from our point of view, body measurements such as stature, weight, strength, etc., are indices of particular physiological developments for which we have no sure means of recognition, variation in period as expressed by a measurement must be the variation in period at which a particular physiological status is attained. We should therefore expect a correlation between such measurements and any recognizable physiological status, and further that this correlation would depend upon the rate of growth.

I have investigated the extent to which this holds for dentition and stature among the Porto Rican boys. If there is a correlation between dentition and stature, then at a certain age those indi-

viduals accelerated beyond the average dental stage of their age should show a greater average stature than the remaining individuals. For example, eight-year boys with permanent upper canines are more developed than their age-mates who lack these teeth: as accelerated individuals, the group with canines should have an average stature greater than that of the group without canines. Similarly, a group lacking deciduous canines should be taller than a group of the same age with these teeth.

Grouping the boys according as they have or have not a particular tooth, and finally taking all the teeth together (that is, weighing the stature of each individual according to his dental pattern), I found the following average statures and variabilities for the accelerated and the retarded groups:

TABLE V: STATURES OF ACCELERATED AND RETARDED GROUPS ACCORDING TO DENTAL PATTERN.

| Age. | Retarded group. | Accelerated group. |
|------|-----------------|--------------------|
| 7 | 1142 \pm 52 | 1146 \pm 56 |
| 8 | 1179 \pm 49 | 1178 \pm 56 |
| 9 | 1247 \pm 41 | 1259 \pm 45 |
| 10 | 1259 \pm 61 | 1282 \pm 68 |
| 11 | 1286 \pm 61 | 1315 \pm 54 |
| 12 | 1348 \pm 71 | 1384 \pm 74 |
| 13 | 1303 \pm 90 | 1394 \pm 76 |

After the ninth year the average statures of the two groups differ, the absolute difference increasing to the fourteenth year. Thus, merely by this relatively rough test, separating the boys grossly according as teeth were present or not, we discover the close correlation between the physiological status as indicated by dentition and a body measurement like stature. A much more subtle statistical analysis could be made of this problem if we had metrical observations for the entire course of development of each tooth. To test these results I treated the data for Channing and Wissler's Bos-

ten school children in a similar way for both stature and weight, with confirmatory results, and the same results were obtained in an earlier investigation by Dr. Crampton.

Here we have a sample of the kind of physiological variation which occurs in dentition measured on the scale of stature. The scale of stature is that of the normal course of growth, represented by the average statures for the whole group of boys year by year. Transforming the statures for the retarded and accelerated groups into years (for example, we can interpolate the stature 1303 in a table of average statures and find 10.8 as the corresponding age), we obtain equivalent "physiological ages":

TABLE VI: PHYSIOLOGICAL AGE OF ACCELERATED AND RETARDED GROUPS.

| Chronological age. | Physiological age. | |
|--------------------|--------------------|--------------------|
| | Retarded group. | Accelerated group. |
| 7 | 7.0 | 7.0 |
| 8 | 8.0 | 8.0 |
| 9 | 8.9 | 9.3 |
| 10 | 9.3 | 10.2 |
| 11 | 10.3 | 11.2 |
| 12 | 11.5 | 12.7 |
| 13 | 10.8 | 13.1 |

These figures give a clearer insight into the meaning of the differences found. Physiological development in dentition varies among these boys to such an extent that boys with retarded dentition and whose actual or chronological ages are 13 years are physiologically only 10.8 years of age!

"Physiological age" is therefore a surer expression of a child's development than his chronological age. Similar observations on the correlation between physiological status and body measurements—such as those of pubescence with stature, weight, strength, lung capacity, growth of the head and face, and mental development as indicated by school

standing—made by Boas, Crampton, and Deaver, have emphasized the point that "physiological age" is more significant than actual age.

Do these extreme physiological variants represent abnormal types? Are we now in a position to draw a line between the normal variant and the pathological individual? At first blush it would appear that an individual who physiologically was only 10.8 years after having lived for 13 years must be a pathological type. But our first caution is that we know that had this individual's status been fixed by dentition alone, instead of by dentition and stature, he would probably have differed less from his age-mates. This leads us to seek for the true meaning of physiological variation.

The illustration previously used of balls in a bowling alley showed us that the degree of scattering or variation from their average position depends on their speed: by analogy the variability among children depends on their rate of growth. At the beginning of the sharp declivity the previously accelerated balls shot ahead, their variability increasing beyond that of the lagging retarded balls. By the time the accelerated balls entered on the final rising stretch and slowed up with decreased variation, the retarded balls were on the declivity, and their scattering, in turn, was greater than that of the accelerated group.

So among the children at the beginning of the period of rapid increase in the rate of growth, the accelerated individuals must be growing at a higher rate than the retarded individuals of the same chronological age but who have not yet entered into the period of rapid growth. Conversely, at the end of the period of rapid growth the accelerated individuals must grow at a slower rate than the retarded. Consequently, at the beginning of the period, accelerated individuals must vary more than retarded individuals from the average of their age, and less at the end of the same period. We have compared below the variabilities of the retarded and accelerated groups of each age:

TABLE VII: VARIABILITIES OF THE ACCELERATED AND RETARDED GROUPS.

| Age. | Retarded group. | Accelerated group. | Difference. |
|------|-----------------|--------------------|-------------|
| 7 | 52 | 56 | + 4 |
| 8 | 49 | 56 | + 7 |
| 9 | 41 | 45 | + 4 |
| 10 | 61 | 68 | + 7 |
| 11 | 61 | 54 | - 7 |
| 12 | 71 | 74 | + 3 |
| 13 | 90 | 76 | -14 |

While the results are not marked, the accelerated group varies more than the retarded group at first, but the relations are reversed at the end of this period. Considering the group as a whole, this means that physiological variation is greatest for all the boys when the rate of growth is greatest, and least when the rate is at a minimum.

Since the amount of variation depends on the rate of growth, we must expect to find that a truly pathological individual stands much closer to the average of his age-group when growth is slight than when growth is great. In other words, if we are to draw a line between the pathological and the normal, the line must vary in position from year to year, being closer to the average during the years of minimum growth, and farther from the average, measuring on the same scale, during the years of maximum growth.

Next we may ask whether the extreme variants at a particular age remain extreme types throughout the course of their development. An answer to this question will determine whether we are to consider a particular case of extreme variation as pathological, or whether we can expect more or less complete recovery to normal type.

While it is true that a close correlation exists between the development of the various parts of the body, nevertheless all organs do not develop at the same rate, so that when one organ has reached a particular stage in its development another may exhibit a certain amount of variability. From this point of view,

the increased variabilities in stature which we found in both accelerated and retarded groups may be an expression of a different rate of development from that of dentition, for if this is so, the greater the degree of acceleration or retardation of dental development the greater will be the variations in stature.

So it follows that what we have been calling the "physiological age," based on the stage of development of one particular organ, by no means represents the physiological development of the body as a whole. Nor can two individuals of the same "physiological age" be considered as physiologically identical, since they are identical in one characteristic only. Furthermore, and most important, chronological age cannot be left out of the reckoning. It is not the same thing whether an individual is "physiologically" 10.8 years old when he is only 9 years chronologically or when he is 13. In the first case, as an accelerated individual he represents a stimulated condition; in the other he represents the depressed physiology of the retarded.

If we trace the course of growth in stature, for example, we find that the boys who grow rapidly before the interval 14-15 years grow slowly later on, while those who grow slowly before that time later grow rapidly. If this were not so, we should find the accelerated individuals continuing to grow rapidly into giant types, while the retarded would grow up pigmies, whereas we find that the ultimate variation in the adult is relatively small. Still, this recovery toward the normal type does not take place in the same way in all individuals. For example, if one group of children attains a certain status in the development of some particular feature at 10 years, while another group attains the same status at 14 years, the former will take longer than the latter to attain the full development, the rates of growth proceeding in entirely different ways.

When acceleration of growth does begin late in life among the retarded, the whole energy is expended in a very short time, the rate of growth far exceeding that of normal individuals. But it seems

fairly clear that the recovery to normal type is not completed in this short period of rapid growth; excessively retarded individuals remain underdeveloped. Since the subsequent development of individuals of apparently the same physiological status proceeds variously, we cannot put a finger on the extreme variants at any particular age and say, "These are pathological," for while one may continue growth as an extreme type, another may later revert to normal condition. We can say, however, that an individual extremely retarded in late childhood is much more likely to be a true pathological type than one retarded early in childhood. Whether, conversely, early acceleration has a beneficial influence we are in no position to say.

These cautions, then, prevent us from discriminating the pathological from the normal on the basis of our data on dentition. As they stand, they are indicative but not of diagnostic value. Only by a more thorough study of dental development especially in relation with other body characters can such data be obtained.

I am tempted to utilize this opportu-

nity to suggest what data orthodontists are now in a position to supply:

(1) Metrical observations on the course of growth of the teeth in the population at large from the first development of the germ to the final states in both deciduous and permanent dentition.

(2) Parallel observations on the same individuals of the other parts of the body, such as palate measurements, stature, weight, strength, pubescence, ossification, etc., for the purposes of correlation.

(3) Observations of the same sort on the selected group which comes to the orthodontist for treatment, to show the types of variation which are found among avowedly extreme cases. Further, similar observations to show what variations can be effected by the various corrective practices.

In all these observations care must be exercised to separate the data by age, sex, nationality or race, and economic conditions.

Band of a Gold Crown in the Bronchus: Report of a Case.

By CHEVALIER JACKSON, M.D., and WILLIAM H. SPENCER, M.D.,
Philadelphia, Pa.

THE infrequency with which dental appliances and the smaller instruments are by accident aspirated into the bronchi is most remarkable, when we consider the number of cases treated yearly by the dentist. The following case is, however, of peculiar interest to the dental profession:

Case No. Fbdy 653 was brought from a western city with the history of aspirating the band of a gold crown, which had slipped from the grasp of the dental

operator. Some slight coughing immediately followed, but there was no dyspnea. Later in the evening the patient had a severe attack of coughing and expectorated a small amount of blood. Radiographs made on the evening of the day of the accident showed the presence of the gold band in the right main bronchus. The situation was considered an emergency, and an able surgeon made an attempt at removal by oral bronchoscopy in the sitting position, under local an-

esthesia. The introduction of the bronchoscope was rendered difficult by the short neck of the patient, and the entire

it slipped from the forceps grasp and entered the left bronchus, from which he was unable to remove it. The patient

FIG. 1.

Radiograph of the band of a gold crown in the left bronchus. Lateral view.

operation consumed six hours. The surgeon was able to grasp the foreign body, but on attempting its withdrawal

was taken to a hospital, where he remained one week. Great swelling of the neck tissues and tongue, marked dyspha-

gia and odynphagia followed, and the temperature rose to 101.8° F. Patient suffered from frequent coughing attacks, and the voice became very husky, although there occurred no alarming dyspnea.

The patient arrived at Jefferson Hospital on the eleventh day following the accident, the tenth following the unsuccessful bronchoscopy. Condition on admission:

Eyes. Pupils equal. React to light and accommodation. No imbalance.

Throat. Tongue much swollen and motility greatly impaired. Pharynx injected.

Larynx. Intense laryngitis with the presence of exudate and granulation tissue. Motility of the arytenoids much impaired.

Neck. Considerable swelling of the cervical tissues. Few enlarged lymph glands. Thyroid not enlarged.

Thorax. Well formed. Rounded. Walls thick and muscular.

Lungs. Expansion somewhat limited over the upper left front. Percussion note impaired over the upper right and lower left fronts. Breath sounds blowing over the upper right front and in the left axilla. Vocal fremitus and vocal resonance seem unchanged. No râles or friction heard.

Heart. Area of dulness normal. Sounds clear and regular. No murmur, shock, or thrill.

The radiographic report of Dr. David R. Bowen reads as follows:

There is a metallic foreign body in the left lung, I believe at the bifurcation of the lower branch of the left bronchus. This is slightly in front of the anterior plane of the vertebral bodies. There is distinct evidence of considerable pathology in the right lung, particularly in the distribution of the lower bronchial branch, but hardly less marked in the distribution of the middle branch. There is very little evidence of any similar condition of the left lung. (See Fig. 1.)

Per-oral bronchoscopy in Jefferson Hospital with local anesthesia revealed an intense laryngitis and tracheitis with exudate and granulation tissue. The band

(Fig. 2) was found embedded in the left lower lobe bronchus, at the orifice of the posterior branch, and was removed in one minute and forty-nine seconds. The

FIG. 2.

Band of a gold crown removed from the left bronchus.

patient experienced no discomfort and no rise of temperature following the bronchoscopy, and left for his home on the following day.

COMMENT.

The possibility of the aspiration of dental materials into the bronchi, in spite of the infrequency of its occurrence, should always be remembered. It should never be assumed that the foreign body has entered the alimentary tract until a radiograph has proved the fact. Of more particular interest to the medical profession, perhaps, is the view taken with regard to the danger of the presence of the foreign body in the bronchus. From our extensive study of these cases the fact has evolved that if the stay of the intruder is prolonged for weeks or months, suppurative processes are set up in that portion of the lung distal to the foreign body. Signs and symptoms simulating with exactness those of pulmonary tuberculosis develop, and if the foreign body be not removed, a fatal ultimate result is almost certain. Certain organic substances set up a very active and violent inflammation of the bronchi and adjacent lung tissue in a very short time, often immediately after their aspiration, but the above-mentioned course of symptoms is the usual one taken in metallic foreign body cases. The pathologic lung changes are caused partly by interference with drainage of the parts below, and partly by the abrasions and the lessened resistance to infection

produced by the constant irritation of the foreign body.

The entrance of a foreign body into the bronchus should, however, not be considered an emergency, justifying hurried and insufficiently prepared attempts at removal. Time should be taken for ac-

curate radiographic localization, and in addition to this a complete instrumental armamentarium with a trained corps of assistants is necessary for the successful, safe, and expeditious removal of foreign bodies.

1830 SOUTH RITTENHOUSE SQUARE.

Trichlorid of Iodin in Dentistry.

By MILTON J. WAAS, D.D.S., Camden, N. J.

FOR some time the trend of modern antiseptics has been toward the halogen group as proving the most efficient. Particularly since the beginning of the war has this been the case, great progress in war surgery having been made, due largely to the use of the Dakin solutions by the Carrel method. The Dakin solutions are, of course, essentially modified chlorin solutions.

ANTISEPTICS OF THE HALOGEN GROUP.

Antiseptics of the halogen group are germicidal in inverse ratio to their atomic weights. Fluorin cannot be kept in solution, and is moreover extremely caustic to soft tissues. Chlorin is the most efficient of the group, but it is difficult to keep in solution without deterioration in strength. Bromin also has disadvantages which are difficult to overcome. Iodin has been probably even more widely used than any other of the halogen group. It is conceivable, therefore, that a combination of chlorin and iodine would produce the ideal antiseptic. This we have in trichlorid of iodine.*

CHEMICAL PROPERTIES OF TRICHLORID OF IODINE.

Trichlorid of iodine (ICl_3) is, as the name indicates, an atomic compound of

chlorin and iodine having three atoms of chlorin to one of iodine. It is a heavy reddish brown fuming powder, acid in reaction.* It comes in hermetically sealed ounce glass vials, and is freely soluble in water. That it may be used in aqueous solutions is very important, as all antiseptics are most efficient when used in aqueous solutions. Being an atomic compound, it is, moreover, highly ionized in solution and therefore in a most active form.

PREPARING THE SOLUTION.

Certain precautions must be observed in preparing the solution. After making a small opening in the glass vial and weighing out the required amount of powder, the vial must be immediately resealed. This may be very satisfactorily accomplished by melting over the opening a small quantity of paraffin wax. This is necessary because the ICl_3 powder is deliquescent and it is much better to keep it in its original form. No metal should be used or touched in weighing out the trichlorid of iodine, as it attacks most metals energetically and is thereby rendered worthless for further use. As it will also attack the metal of the scales, it is necessary to first accurately balance on the scales a glass-stoppered bottle;

* See *Dental Items of Interest*, March 1918, for test tables of this anesthetic.

* Obtainable from Merck & Co., New York City.

the powder is then dropped from the original vial into this bottle, with the stopper inserted, and weighed. As it is an atomic compound, the solution will disintegrate if not prepared with *distilled* water. The stronger solutions from 1 per cent. up seem to keep for a long time without disintegration. The 1 : 1000 solution, however, should not be kept too long. The three solutions which will be found of greatest use in dentistry are the 25 per cent., 1 per cent., and 1 : 1000.

DISSOLVING BROKEN-OFF STEEL INSTRUMENTS.

The 25 per cent. aqueous solution is used for the purpose of dissolving broken-off steel instruments of any sort which may be found in root-canals and which cannot be dislodged by mechanical means. Only tantalum- or platinum-pointed instruments or a platinum-pointed dropper or syringe should be used in applying the solution. The action of ICl_3 when it comes in contact with steel or iron is to form ferrous iodid and ferrous chlorid, both of which salts are soluble in water. Its action is definite and very rapid if sufficient surface of the metal is exposed, and may be tested by dropping a broach in a little of the solution. In a canal, however, it has only the cross section of the broken metal to attack and it will often require more than one visit and patient technique to either reduce, say, a broken broach sufficiently in circumference so that it will drop out of the canal, or to entirely dissolve it.

Therefore it is necessary to drill around the exposed end as much as is safe, so as to expose as much metallic surface to attack as possible. Apply a small quantity of the 25 per cent. solution of trichlorid of iodine around the broach in the canal and allow it to remain for three minutes. Absorb this with paper points, wash out with distilled water and dry around the broach with cotton wound on a broach, removing any remaining ferrous coating. Dry with air-blast and pick around the instrument with Rhein picks. Apply ICl_3 again for

three minutes; absorb, wash, dry, pick and enlarge the space around the instrument again, and repeat until the entire obstacle is removed.

PRECAUTIONS IN USING THE TWENTY-FIVE PER CENT. SOLUTION.

If the tooth under treatment is an anterior tooth, where any discoloration must be avoided, the best procedure is to flow a small quantity of melted paraffin over the dentin which lines the labial enamel—in other words, the labial coronal dentin. This will not interfere with the action of the ICl_3 in the canal, and the crown of the tooth will not be stained. In posterior teeth, if there is any reason to remove the stain, it can be best accomplished by applying a strong aqueous solution of ammonia followed by a saturated aqueous solution of sodium hyposulfite.

In 25 per cent. solution, ICl_3 penetrates the dentinal tubules rapidly and deeply, and is one of the most potent germicides known. It is, however, in such strength, quite caustic to the soft tissues, and must not be allowed to pass beyond the apex.

USES OF THE ONE PER CENT. SOLUTION.

A 1 per cent. solution, therefore, is the one of choice for use where the preparation will come in contact with soft tissue—to which, in this strength, it is not caustic and still is a remarkably effective germicide, containing almost the same percentage of available chlorine as the Dakin sodium hypochlorite solution. This solution has been found to destroy all tested mouth bacteria, including the streptococcus, in fifteen seconds. Whether it works quicker than this the writer does not know, as that was as rapid as the test tubes could be properly manipulated.

Used in an all-glass syringe with a platinum point, such as the Sausser irrigator, it is very valuable for washing out root-canals, fistulous tracts, sockets after extraction, cavities left after apicoectomy operations, and pyorrheal pockets. It will effect an almost immediate surface

sterilization. Being a highly ionized compound, it delivers up its available chlorin and iodine to the tissues at once. While its action when injected via an open root-canal into a granuloma or cystic cavity should be valuable, it would have to be repeated frequently to be sufficient to cure such a condition. To seal such a solution in a tooth as a dressing would be valueless, as its strength would be dissipated immediately.

SOLUBILITY IN CHLORCOSANE.

To those who, for any reason whatever, are not using "ionization" for this purpose, it might be interesting to know that I have found ICl_3 soluble in chlorcosane. Chlorcosane is Dakin's new single solvent for dichloramin-T, and is quite generally on the market. It is paraffin made liquid by having chlorin forced into it to the point of saturation. Most of the coal-tar compounds are quite permanent and give a bland solvent for chlorin-containing substances. Most other solvents readily take up chlorin and so destroy the effectiveness of the final solution. The chlorin in the chlorcosane itself has entered into permanent combination and has no action on tissue, as its chlorin is not available. ICl_3 in solution in chlorcosane might prove valuable to seal in an infected root-canal as a dressing, as in such an oily solution its available chlorin and iodine are but slowly given off and would act over some period of time. The writer has used this preparation

with satisfaction, but only in a few emergency cases, relying on ionization in routine canal work, and, as before mentioned, it is offered as a suggestion for trial to those who have not adopted the former method. It is also worthy of note that ICl_3 is amœbicidal as well as germicidal when used in pyorrheal pockets. Painted on the mucous membrane it will give a sterile surface for the introduction of a hypodermic needle without having the caustic effect of tincture of iodine.

USES OF THE ONE-TO-ONE-THOUSAND SOLUTION.

In the 1:1000 solution, with the addition of saccharin to improve the taste, it is by far the most efficient germicidal mouthwash ever used. Used before and during the curetment in pyorrheal treatment and for a period of one or two weeks after, or until the acute inflammation and infection is controlled, it will be found of the greatest assistance. Even those who have heretofore been skeptical of the value of mouthwashes will be convinced of its aid if it is employed a few times. The solution should be freshly made and used warm every two hours, if possible. It will also be found valuable as a gargle in infected throat and tonsillar conditions. It is somewhat acid in reaction, and on this account its use should not be continued indefinitely, but it can be safely used for the time mentioned.

Care of Children's Teeth.

By H. ANHAEUSSER, D.D.S., Peking, China.

PERMIT me to submit a few thoughts concerning the treatment of children's teeth and the care of the child during operation which I consider very important, and which are not often brought out in dental magazines.

I found children quite a trial to me in my early days of practice, and the experience I had with them and my present procedure may be of value to someone else working under similar circumstances. My personal recollection of visiting the dentist, as a small boy, is still very fresh in my memory, and will remain there until my last day. I was taken to a dentist whom I considered as an unfit person for his vocation, and only by brutal force was he able to complete the operation he was to perform. The same man never operated on me afterward; the fear instilled in me at that time was too great to be overcome even in after years.

Our little patients need more care and forethought than our older ones. A certain amount of confidence must be obtained before we can even begin with the operation; the child's trust must be obtained, and this can only be done very slowly, so that he will not be conscious of it or realize the object. To attain this, I have made it a rule to have the small patient prior to the treatment brought to the office to see me several times either by one of the parents or the nurse while out for their walk. A casual conversation of short duration is indulged in, and after a few days this is repeated, until the child is gradually shown into the operating-room. If time permits the chair is explained to him, or possibly the engine, until the fear of the office has passed, and an enthusiasm is

worked up in the little one so that he feels eager to undergo the same operations as the older ones and does so without giving the operator any difficulty whatever in performing some of the most intricate operations performable on the rising generation.

This practice prevails in cases where there is nothing urgent—where only a thorough examination, with possibly one or two little cavities to be filled, is required. In cases where a severe form of odontalgia is present and requires immediate attention to alleviate the pain, I use a sedative at the first visit, and allow the patient to come back later on for the final operation.

Abscesses to be opened at the first sitting have been a great problem to me for some time, and caused a lot of annoyance until I used a method which I found to be excellent, not only with the little ones, but also with those more advanced in years who still have a fear of dental instruments.

I first examine the case without any instruments in sight. Then I select the instruments wanted for that particular operation, not allowing the patient to see anything that has been selected, and give them to my assistant for sterilization. Each instrument is brought in wrapped in a piece of cotton to conceal its identity as to the point, only the handle being exposed. The knife has the cotton wrapped about it very loosely, so that it has the appearance of an ordinary swab used for throat cases. Before it comes to me the assistant has worked this cotton sheath back and forth once or twice, to insure proper working, and to avoid any interference when I have to use it.

From all instruments I am to use the

cotton wrappings are removed as required in their proper order. From the concealed knife, however, the "camouflage" cover is not removed. This is introduced and its cover removed within the mouth by means of the index finger, pulling the cotton toward me, which leaves the blade of the knife free for working. So far I have had no difficulty whatever with my little patients, as by the time they begin to realize what has happened, the operation is over, and invariably so much relief is experienced that the thought of what really has happened to them is expelled from their minds. A pleasant conversation is immediately indulged in; I think almost everyone in the profession has plenty of such in store to expedite the discharge of the patient for that day's sitting.

As an anesthetic in these cases I generally use a small pellet of cotton dipped in carbolic acid, and applied until I have the spot where I intend to make the incision well under the anesthetic effect. Anesthetics which require a certain amount of preparation I do not use for these cases, as it means too much of a nervous strain for the patient, and makes the final operation very difficult. I have noticed when I formerly resorted to more active anesthetics that it was almost impossible for me to use them, and by the time my little patient was willing and submissive the anesthetic had lost its virtue, and the effort I had spent only resulted in making the child very nervous and setting for myself a more difficult task. There was also a great loss of valuable time, which means nothing to a child, and at the end I was unfit to go on with another patient. In our nerve-racking vocation a good deal of thought should be given to regulating our procedure in such a manner that we not only do justice to our clients, but also consider ourselves a little, and especially our *nerves*.

TREATMENT OF SMALL CAVITIES.

In treating small cavities where the decay has just penetrated the enamel, I resort to the application of a solution of

nitrate of silver. I never use the lunar caustic stick in the mouth direct, for the simple reason that the mouth in cases of this sort is so bathed in saliva that it is impossible to keep the saliva from flowing into the cavity, and the final result will be that the whole mucous membrane of the mouth will bear evidence of the presence of AgNO_3 —a very undesirable result. I use a small pellet of cotton between the beaks of a pair of tweezers—especially kept for that purpose and for the use of other escharotic drugs—moistened with water, then rubbed across the caustic stick until fully saturated. This I carry to the cavity and swab it out thoroughly, repeating this procedure two or three times until the desired result is obtained, each time using a fresh piece of cotton. Should this be considered sufficient, the patient is discharged. A record of the case is made, put on file, and at the end of three months the small patient returns for observation.

TREATMENT OF CAVITIES WITH PARTIAL DESTRUCTION OF DENTIN.

If I find that the decay has been progressive, irrespective of the former precautions taken, and has penetrated the dentin, I again resort to the AgNO_3 , which in its action closes all the dentinal tubules, when all or most of the decay can be removed without any appreciable pain to the individual (I refer to deciduous teeth), by means of a sharp excavator. Repeat the application if necessary. By means of chisels, trim the margins, and fill with any suitable material. Allow yourself plenty of time and give the patient a sufficient amount of rest between each step to avoid tiring him.

PULP EXPOSURE.

The majority of our cases not under regular treatment and observation are most in need of our services at a time when pulp exposure has already taken place, due in many instances to lack of observation by the parent. I have also found many cases in which delay in treatment has been advised by their fam-

ily physician—of the old school, which still labors under the impression that children's teeth require no attention with the exception of having them *pulled* if any decay is present or discomfort of any sort arises.

If the case is such that the pulp is completely destroyed, the case is simple to treat, and I proceed as follows: With lukewarm water, the cavity is gently flushed out to clear it of all débris. With a very dull excavator I remove the adherent particles clinging to the sides of the cavity, and again flush until the cavity is thoroughly clean and the field is clear for good observation and exploration to ascertain if any vital part of the pulp is still present. Should this be the case, I fill the respective root-canals with either carbolic acid or creasote on a small pledget of cotton, and seal the whole with a temporary stopping, making it smooth with a small amount of chloroform. After two or three of these treatments the remaining vital portion of the pulp will be in such a condition that it can be removed without any pain whatever. Too much care as to the absolute and total removal of the smallest particle of pulp is not necessary. It is more important to see that the cavity is clean, and kept so during the operation and filling.

My next step is to fill the root-canals with a substance which can be absorbed with the rest of the tissues during the physiological process of eruption of the new tooth, and at the same time contain some disinfectant to avoid recurrence of infection. By means of a small probe I insert a small amount of aromatic iodoform paste, and carry it down as deep as possible without producing pain; then I use the ordinary base-plate paraffin wax to complete the filling of the root-canal. Over this is placed a layer of cement, after which the regular filling material is inserted to complete the operation.

EXTRACTION.

One of the most difficult operations to undertake in our practice with little pa-

tients is the extraction of their teeth, especially when the permanent teeth erupt irregularly.

Most of these extractions can be done with very little anesthesia. I also find it much better not to have the mother accompany the child whenever the extraction is to take place, as the child will be braver and much easier to handle. The small deciduous tooth forceps are so ingeniously made that under ordinary circumstances they can be well concealed within the palm of the hand, and be ready for use at the proper time.

FILLING MATERIAL.

As to filling material for children's teeth, I use alloy, cement, and gutta-percha. Each has its place, and whenever judiciously used satisfactory results will be obtained from either. The theory taught during college days, namely, that gutta-percha was the only material to use in children's teeth, I have long forgotten. I found it inadequate in some of the cases, and advantageous in others.

In teeth where a portion of the crown has been destroyed due to existing caries, and its adjacent neighbor encroaches upon the space, gutta-percha should be used until the proper alignment is restored. The gutta-percha filling should then be taken out and alloy substituted. One great fault I find with gutta-percha when used as filling material in approximal cavities is that it is often forced against the gum and produces an irritation; this can be avoided by using a metal filling.

I use cements in small cavities on the buccal or occlusal surfaces. The cavities can be easily kept under observation in case the cement washes out.

I *never* use cement in any cavity extending to the gingival line, either in children or in adults. In each case the filling will be found in excellent condition at the occlusal surface, and partially or totally washed out at the gingival border. I have never seen it fail to do this.

Root Amputation:

Being the Report of the Correspondent, Dental Society of the
State of New York.

By ARTHUR W. SMITH, D.D.S., Rochester, N. Y.

(Read before the fiftieth anniversary meeting of the society, Saratoga Springs, June 13, 1918.)

THE subject of root amputation was selected for the Correspondent's Report this year because it has a close relation to two branches of the profession which are receiving constantly increasing attention at the present time—focal infection and oral surgery.

A letter and list of questions were sent to 52 general practitioners and oral surgeons throughout the country. Eighteen complete and ten partial replies were received from men in all parts of the country. To avoid repetitions and excessive length only a general summary, and a few quotations will be given.

It is interesting to note that a rather wide diversity of opinion exists on certain phases of the subject. Even the technical name for the operation seems debatable. Several good authorities, including Ottolengui, Kells, and Silverman, use the term apicoectomy, while Blum, Rhein, Burridge, and others are using the contracted form apiectomy.

QUESTIONS.

(1) Do you consider root amputation advisable in any case?

(2) A. In what cases or conditions?

B. On what teeth (anatomically)?

(3) A. What do you consider the best filling to use in a root-canal previous to amputation?

B. Why?

(4) A. In what percentage of your cases have you had a normal regeneration of the bone following the operation?

B (the reverse of A). In what percentage has the apical area failed to recover?

C. To what do you attribute these failures?

(5) Do you advocate the use of (A) the bur, (B) the chisel, or (C) both the bur and chisel for removing the root apex?

(6) If you radiograph the tooth at intervals after the operation, what have you found to be the average time (in months) in which bone regeneration has taken place?

(7) A. Do you consider it advisable to suture the incision after operation?

B. If so, what are the advantages?

C. If not, what have you found are the objections?

(8) A. Should the operation be performed by the general practitioner or by a specialist?

B. Why?

SUMMARY OF ANSWERS.

QUESTION 1—*Do you consider the root amputation advisable in any case?*

"Yes," answered by 14. "Occasionally," answered by 1. "In rare cases," answered by 1. "No," answered by 2.

The last two are quoted in their entirety.

(Quotations from answers.)

April 17, 1918.

My dear Dr. Smith,—Replying to your favor of the 10th, would say that I have not practiced "apicoectomy" for twenty-five or thirty years, and naturally what I did that long ago doesn't count.

The reason I discontinued the operation was because of its unsatisfactory results. The reason I have not taken it up recently,

since it has become a fad, is because I could not do it in a manner to satisfy myself.

I have seen a number of *very prominent* clinicians perform it, and not one have I seen whose work I would care to duplicate. Every now and then a case comes in having been operated upon by some prominent man in the North, and every single case so far seen has been unsatisfactory.

During all these years I have practiced replanting, which I can do satisfactorily. Possibly some of these days I will "catch on" to some trick by which I can apiectomize teeth to my own satisfaction, and then I will switch over to apicoectomy.

In an early issue of the *Cosmos* I will have a paper treating this subject, which I hope you will read, and I would appreciate your criticism of it.

Yours very cordially,

C. EDMUND KELLS.

April 22, 1918.

My dear Doctor,—As I am no longer a believer in apiectomy I do not think it is necessary for me to answer your questions, but I shall endeavor to state very briefly why I believe these operations are a failure. In my opinion the percentage of successful cases of root amputations is extremely small. I question very much if there is ever a normal regeneration of bone following these operations; at least I am convinced, from the investigations I have made that an attachment of tissue to the root-end never takes place, which is, I believe, the chief cause for the failures. I do not regard radiographs as being conclusive evidence, as it is not possible to disclose minute changes or disease tissue that may exist, neither is it possible to determine by a radiograph if there is a regeneration of bone in the rarefied area or if dense bone around the rarefied area has resulted from the activity of the osteoblasts in the deposit of osseous tissue in the cancellous portion of the bone. These results can be produced by the stimulating of the osteoblasts by the use of certain remedies.

Trusting this will explain my position regarding the question, and answer your inquiry, I am

Yours very truly,

CARL J. GROVE.

QUESTION 2 (A)—*In what cases or conditions?*

(Quotations from answers.)

Major Robert H. Ivy: "Teeth showing areas of periapical bone destruction with granu-

loma, suppuration, or cyst formation where not more than the apical third of the root is involved, and where the general health of the patient does not demand more certain and rapid elimination of the focus of infection."

M. L. Rhein: "In such teeth where, after filling the root-canals, it has been found that encapsulation of the periapical ends of the roots has not been attained; in such cases of old infections where the ends of the roots themselves are necrosed; where a broach or other broken instrument may protrude through the end of the root; where some abnormality has produced nerve pressure at the end of the root; other conditions that may present pathologic features that have not been able to be remedied by correct root-filling."

(B)—*On what teeth (anatomically)?*

A great diversity of opinion seems to exist here. All were agreed on the six upper anterior teeth.

(Quotations from answers.)

Earl Brooks: "The ten upper anteriors."

C. H. Oakman: "All single-rooted teeth."

A. M. Nodine: "This operation may be performed on the following teeth, depending upon accessibility, anatomical considerations, and the experience and skill of the operator: About in the order of difficulty of operation and frequency, upper and lower centrals, laterals and cuspids; lower first molars, upper bicuspid, lower bicuspid, upper first molars, lower second molars, and upper second molars."

Theodor Blum expressed the opinion of the majority, however. He said:

"Apiectomy can be performed on all teeth if the apical area is accessible. Ordinarily, only the teeth up to and including the second bicuspid are considered."

QUESTION 3 (A)—*What do you consider the best filling to use in a root-canal previous to amputation?*

Four stated the Callahan method. One specified gutta-percha and chloro-percha, one gutta-percha and eucalypta-percha, and one oxid of zinc cement. Seven said "Gutta-percha," implying the use of either chloroform and rosin, chloro-percha, or eucapercha as the solvent.

(B)—*Why?*

The majority answered that it hermetically seals the tubuli and foramina.

(Quotations from answers.)

Dr. Oakman: "Habit, I presume; never used anything else."

Dr. Nodine: "(1) It is congenial to the tissues. (2) It shows clearly in the X-ray. (3) It may be made to fill the root-canal perfectly. (4) It shows at the point of cleavage and acts as a guide when the root-end is separated from the larger part of the root."

QUESTION 4 (A)—*In what percentage of your cases have you had a normal regeneration of the bone following the operation?*

(B) (the reverse of this)—*In what percentage has the apical area failed to recover?*

Here the replies were necessarily vague and inaccurate, but the questions were asked for the purpose of obtaining some idea of the number of successes or failures one might expect.

Estimations of successful cases varied from 98 per cent. as recorded by Blum, 95 per cent. by Thoma, 90 to 95 per cent. by Furnas, 90 per cent. by Brooks and Nodine, 75 per cent. by Rhein and Ivy, 60 per cent. by Moorehead, down to practically zero by Kells and Grove.

(C)—*To what do you attribute these failures?*

(Quotations from answers.)

Dr. Furnas: "Bad technique."

Dr. Percy Howe: "Lack of vitality in peridentum."

Dr. Blum: "First, operating on badly filled roots (reinfection), and second, using the chisel for removing the apex (root was split and had to be removed about a year later)."

Dr. Brooks: "Reinfection either from root-end or hematogenously, usually the former."

Dr. Moorehead: "Failure may be attributed to faulty technique, both in the operation and more especially, I believe, in the management of the root-canal. The regenerative capacity of the patient is a large factor."

Dr. Oakman: "In trying to do too much, or endeavoring to save teeth which should be extracted."

QUESTION 5—*Do you advocate the use of (A) the bur (B) the chisel, or (C) both the bur and chisel for removing the root apex?*

Ten advocated the use of the bur only. Four advocated the use of both the bur and chisel. One (Dr. Silverman) advocated the chisel alone.

QUESTION 6—*If you radiograph the tooth at intervals after the operation what have you found to be the average time (in months) in which bone regeneration has taken place?*

The average time given was six months. The minimum three months. The maximum fourteen months.

QUESTION 7 (A)—*Do you consider it advisable to suture the incision after operation?*

Twelve answered "Yes." Five answered "No."

(B)—*If so, what are the advantages?*

(Quotations from answers.)

Dr. Blum: "Shorter period of treatment; less pain."

Dr. Moorehead: "The immediate closure of the wound lessens the amount of scar tissue and insures a better contour. Where immediate closure is practiced, however, it is necessary at times to irrigate with a sterile normal salt solution. We have practiced both methods, and find that immediate wound closure in our hands is the more satisfactory method."

Dr. Rhein: "This is done to obtain healing by first intention. The same object can be obtained by placing an antiseptic dressing over the mouth of the wound, which will exclude oral secretion until protoplasmic cells have formed over the entrance of the wound. This method has a decided advantage over suturing, and accomplishes the same purpose. I believe it is original with myself and is not generally understood. The operation is a much simpler one than generally expected, and any competent general practitioner should be capable of performing the same."

(C)—*If not, what have you found are the objections?*

(Quotations from answers.)

Dr. Howe: "Unnecessary surgery."

Dr. Moffitt: "Suturing interferes with handling of gauze in inducing healing from within outward. For a single root only a small incision is necessary."

QUESTION 8 (A)—*Should the operation be performed by the general practitioner or by a specialist?*

Here again was a marked divergence of opinion. Seven answered, "By the specialist." Four answered, "By the general practitioner." Three answered, "By either."

(B)—*Why?*

(Quotations from answers.)

Dr. Moorehead: "Any form of surgery had better be done by a qualified surgeon. The general practitioner of dentistry is quite as competent to do oral surgery as the general practitioner of medicine is competent to do general surgery, but the individual who is giving his thought and attention to surgery, and is living in the atmosphere all the time, all things being equal, is more likely to get satisfactory results than the individual who is giving almost all of his time and thought to general practice."

Major Ivy: "The operation should only be employed by the surgical specialist, because he is accustomed to operating under aseptic conditions essential for the best results, and is better prepared to handle the cases. The technical requirements of the operation demand experience in this work gained only by constant practice."

Dr. Furnas: "The day is coming when the general practitioner will do this work, but now there is a big question of technique, ability, and equipment involved."

Dr. Nodine: "It may be performed by the general practitioner provided he has the equipment, experience, and skill, and is careful and thorough in his work and does not attempt hopeless cases. Unless he possesses these requirements or qualifications it had better be left to the specialist."

Dr. Howe: "Simple thing; any dentist can do it."

GENERAL CONCLUSIONS.

There seems to be good authority for employing either the term "apicoectomy" or "apicectomy" in speaking of the operation of amputating the root of a tooth.

The majority of dentists consider apicoectomy advisable in cases of chronic

apical infections where the bone, periodontal membrane, and not more than the apical third of the root are involved.

The six upper anterior teeth are apicetomized most easily, the lower anterior ten and upper bicuspids less easily, and the molars with difficulty.

Gutta-percha is recognized as the best material for filling the root-canals. The use of chloroform and resin, chloro-percha, or eucapercha in conjunction with the gutta-percha seems to be a matter of choice with each individual.

Where the operation has been followed by check radiograms the operators report a moderately high percentage of successes.

Failures are reported as due to faulty technique, low vitality of surrounding tissue, and reinfection.

For removing the apex of the tooth the bur is given preference over the chisel.

Six months is the average time given for the complete regeneration of bone in successful cases. The time varies with the age and vitality of the patient.

Suturing of the incision is recognized as the preferable method of closing the wound, as it tends to hasten the healing, prevent reinfection, and lessen the after-pain. In cases of extensive involvement packing is advocated.

Opinion is well divided as to whether apicoectomy should be performed by the specialist or the general practitioner. It is generally conceded, however, that unless the general practitioner is well equipped, has a thorough knowledge of asepsis, and has developed a skilful technique, the operation should be performed by the specialist.

The Correspondent wishes to express his appreciation on the behalf of the Dental Society of the State of New York for the comprehensive replies received, from which he was enabled to compile this report.

CORRESPONDENCE

Sulfuric Acid in Root-canals.

TO THE EDITOR OF THE DENTAL COSMOS:

Sir,—In your June issue, Dr. Waas, writing on the use of acids and of sodium and potassium in root-canal work, says: "With acids we might have considerable destruction of tissue, as the acid is drawn up by capillary attraction and is *not self-limiting in its action, as is sodium and potassium.*"

The late Dr. Callahan in his article on the use of sulfuric acid in root-canal work (*Items of Interest* for August 1915) tells us, and shows an illustration

of cancellous tissue exhibiting the action of both agents to prove, that *sulfuric acid is self-limiting*, while sodium and potassium is not.

Will you be good enough to print this in your journal and see if we can interest some of our investigators in this line of work, in order to establish once and for all who is correct?

Very respectfully,

SAMUEL J. KESSLER, D.D.S.

NEW YORK, August 23d.

Professional Capability and Dental Commissions.

TO THE EDITOR OF THE DENTAL COSMOS:

Sir,—Your editorial in the August number of the DENTAL COSMOS inspires one with a feeling of optimism and confidence in the future welfare of dentistry as a profession. The opportunities offered the profession in the present war should be welcomed and taken advantage of, especially by those in the army and navy services. The men serving in the dental corps of the army and navy are representatives of the dental profession, and upon them rests the responsibility of demonstrating the capabilities and importance of that profession. Thus it is to the interest of the profession, as well as to that of the men being treated, that the most capable men be selected for service as dental surgeons in the army and navy. Unfortunately there have been many instances of injustice and

inefficiency in the choosing of men for commissions in these departments, so that today many dentists with valuable experience are serving as privates, while inexperienced, newly graduated men are wearing the officer's uniform. I have in mind at the present time three young men who have served hospital internships; each has received training not only in every branch of dentistry, but also in anesthesia, surgery, and medicine: Two of these men are now serving as privates, while the third is awaiting his draft call.

I have in mind also the system of examination of candidates for dental commissions in the navy, which allows the disqualification of men like the above-mentioned and the acceptance of inexperienced, inefficient 1918 graduates. I might also mention the fact that, in spite of many vigorous assertions to the effect

that no more commissions could be granted in the army dental reserve corps, four men of the '18 class of one of our dental colleges have received commissions. This, of course, is not only unfair to those who have been trying to obtain commissions since the call for dentists was issued, but is also unfair to the profession as a whole, as it sends forth inexperienced men as representatives when the services of better qualified men could be secured. Many of the dentists now in the service have already shown ineffi-

ciency and will probably in time be eliminated; but, had more care been exercised in the selection of dental officers, this elimination would not now be necessary.

Dentistry is destined to make an enviable record in this war; let us hope that this record will be marred as little as possible by occasional mistakes involving injustice and inefficiency.

Very truly yours,

R. A. CLARK, D.D.S.

PHILADELPHIA, PA., August 19, 1918.

Procain and Novocain Identical.

[Reprinted from the Correspondence department of the *Journal of the American Medical Association*.]

TO THE EDITOR:

It appears that in certain quarters the attitude is taken that the local anesthetic sold as Procain is not identical with that marked as Novocain. The Subcommittee on Synthetic Drugs of the National Research Council believes it important that this misunderstanding should be corrected, and hence offers the following explanation:

The monohydrochlorid of para-amino-benzoyl-diethyl-amino-ethanol, which was formerly made in Germany by the Farbwerke, vorm. Meister, Lucius & Bruening, Hoechst a/M., and sold under the trademark name "Novocaine," is now manufactured in the United States. Under the provisions of the Trading with the Enemy Act, the Federal Trade Commission has taken over the patent that gave monopoly for the manufacture and sale of the local anesthetic to the German corporation, and has issued licenses to American concerns for the manufacture of the product. This license makes it

a condition that the product first introduced under the proprietary name "Novocaine" shall be called Procaine, and that it shall in every way be made the same as the article formerly obtained from Germany. To insure this identity with the German novocain, the Federal Trade Commission has submitted the product of each firm licensed, to the A. M. A. Chemical Laboratory, to establish its chemical identity and purity, and to the Cornell pharmacologist Dr. R. A. Hatcher, to determine that it was not unduly toxic.

* * * * *

In conclusion: Procain is identical with the substance first introduced as Novocain. In the interest of rational nomenclature, the first term should be used in prescriptions and scientific contributions.

JULIUS STIEGLITZ, Chicago.

Chairman,

Subcommittee on Synthetic Drugs,
National Research Council.

PROCEEDINGS OF SOCIETIES

Dental Society of the State of New York.

Fiftieth Annual Meeting, held at Saratoga Springs, N. Y., June 13-15, 1918.

(Continued from page 815.)

THURSDAY—*Afternoon Session.*

The meeting was called to order at 2.30 o'clock by the president, Dr. Rich.

The President introduced as the first speaker of the afternoon Dr. B. HOLLY SMITH of Baltimore, Maryland, who read a paper entitled "The Past and Present of Operative Dentistry."

[This paper is printed in full at page 884 of the present issue of the DENTAL COSMOS.]

DISCUSSION.

Dr. R. Ottolengui, New York. There is one great difference between Dr. Smith and myself—there are a number, of course, but I mean one to which I particularly would call attention: He admitted today that he does not like to hear me talk, whereas I just love to hear him talk. The main satisfaction I had in finding my name on the program to discuss Dr. Smith's remarks was that I would necessarily be present to hear them.

I wish to correct an opinion that I see is in your mind. Telepathically I feel you think there is an antagonism between Dr. Smith and myself. I thought so myself for a number of years, until I found that Dr. Smith is the living embodiment of the saying, "Whom he loveth he chasteneth." He feels at liberty to say just what he feels for those for whom he has affection. The more he criticizes me,

therefore, the better I like it. After I grew to appreciate that side of Dr. Smith, I got close enough to him to learn more of his real character.

I want to remind Dr. Smith of the Jamestown meeting. Dr. Taggart expounded at that meeting his method of making gold inlays, and a Southern methodistical orator arose and said: "Woe is the day! Today dies all that is artistic in dentistry." I used to live in the South myself, so I got up and said: "Hail is the day! For today is born all the artistic opportunity in dentistry."

Now, what do we find about the gold inlay, and the gold foil filling? We find there is a definite place for the gold foil filling, as well as for the gold inlay, and it takes the same skill, and the same artistic ability, to do one correctly as it does to do the other. I believe that in a small cavity it is almost malpractice to put in a gold inlay. We have no right to cut away good sound enamel and dentin because we find it easier to let our laboratory man make an inlay for us to cement in than it would be to fill it by the methods that we know will make a filling that will stand for twenty-five or thirty years, if we do it correctly. But just in proportion as it becomes our duty to restore an occlusal surface and the true form of the tooth, it becomes our duty to make a gold inlay, and to use the best that is in us in making it.

What shall be our standard of a gold inlay? That every part of the margins shall be as perfect as the best foil filling ever made; and to do that there is no short road, and no easy method, by any means.

To surprise Dr. Smith and the rest of you by not making a long speech, I want to say in conclusion: There is no system in dentistry that is universally applicable, because ours is not a mechanical art. The one pitfall in dentistry is the word "system." We should remember that we are working on living tissue, and there are almost as many variations in human tissues as there are human beings. Some men take six grains of morphin four times a day, and thrive on it; while if another took one-sixteenth of a grain he would die. So it is with all the other tissues of the body. You must be something more than a dentist, more than a mechanic, more than a physician, to determine what is best. We cannot fill teeth with one kind of filling. We cannot say one style of gold is always better than another. We cannot say the inlay is a slipshod method. We cannot say there is only one way of treating a diseased tooth, or that there is only one system of regulating teeth.

Dr. PAUL R. STILLMAN read the Report of the Committee on Practice.

[This report is printed in full at page 893 of this issue of the DENTAL COSMOS.]

DISCUSSION.

Dr. Leuman M. Waugh, New York. In the report, the chairman spoke of the very unfortunate occurrence of over one hundred British soldiers who, through the vomiting incident to seasickness when crossing the Channel while being returned wounded, died of strangulation because they had appliances in the mouth which could not be quickly removed. The appliances, therefore, that we make must be of such a type that they can be readily removed when necessary!

It was said that certain forms of orthodontic appliances would be more efficient and more hygienic and give better results, perhaps, than any we have used.

It is very true that many of us—not only men at hospital centers, but men in little hamlets everywhere—will be called upon, in consultation with physicians, to expand arches and correct malpositions of teeth, because of the mal-adaptation of the parts of a fracture. How can we most readily and easily prepare ourselves for this? It is common knowledge that in all the warring countries abroad the dental profession was called in late, and when called in was absolutely unprepared to take care of the work. Let us start now—it is already late, but we can make efforts to do what we can for the men who are giving their blood and chancing their lives, so we can take care of them when they come home.

I have here a suggestion which I would like to make. The demerits of the suggestion please credit to me, and if it has any merit I shall be very glad. On Saturday, when I left home, we had registered 15,600 men. I am coming more and more to the conviction that there are many men who are working for the Preparedness League who are not registered at headquarters—men who have joined their local units, thinking that made them national members, but it does not. I think we have more men working for the Preparedness League than are in the National Association. Be sure the men who join the local unit have their names and their membership fee of one dollar forwarded to the National Association.

The President. May I ask a question? You speak of the Preparedness League giving their time to United States army men. Do you mean discharged men?

Dr. Waugh. I mean men who are coming home wounded.

The President. The Preparedness League has no access to the man who is not discharged. That man is under the charge of the dental corps.

Dr. Waugh. The idea is for the Preparedness League to get that recognition, and to work as some of the men in New York are now working. I do not know whether I may be allowed to tell, but Dr. Stillman is organizing a unit in which the men are to be given rank. It is

inconsistent with the beneficent service and the work done, not to give them rank.

Those men who can pay for the service rendered are expected to do so. Those men who admit that they are capable of paying are not sent to the League members for service: only those who could not have the work done before they entered the army will receive the work gratis.

Dr. Hayes, who is at the head of the American Ambulance in France, had a great deal of money given to him by some wealthy ladies, for taking care of the wounded soldiers. He would not accept that money until he had sufficient recognition, for the reason that if the dental corps did not have army recognition, a sergeant in the regular army could come around and order the men to do what he wished. We must petition the Government to give us that standing which is consistent with the dignity and the beneficence of the work.

We have wounded men going through New York every day, with legs and arms off, and wounded jaws. They are coming faster than we can take care of them. Are we to prepare ourselves, or are we to admit that we do not know anything about it?

Dr. Frank A. Gough, Brooklyn. The report of the Committee on Practice is of more than usual interest to me this year, and I desire to compliment the committee upon bringing to our attention some very live topics for discussion. Not only is the world approaching its greatest crisis, but our profession is also in the midst of the most critical period in its history, and such time as we may spend here looking to its future will be time well spent.

There can be little doubt that the American orthodontists could be of inestimable benefit in much of the jaw work that is resulting from the war, if some way could only be found to make use of their knowledge and experience. As Dr. Waugh has pretty thoroughly covered that subject, I will omit further reference to it, except to state that I think I can speak for the orthodontists

of America and say they will gladly co-operate in any movement looking toward this end.

I see no reason why the efficiency engineer's suggestion should not bear fruit. It seems to me that with the present interdependence of the medical and dental professions, such a plan might include all the specialties of both medicine and dentistry. Such a movement could not succeed unless it had a real leader at its head, however.

I most emphatically differ with the committee in regard to the proper method of developing a specialist. The very reason that orthodontia has outstripped all other specialties in its progress is because it has a great leader whose influence has been felt to a marked degree even by those who have opposed everything he has ever suggested. Such leadership is needed in every one of the other specialties, if they are to fulfil their proper function.

Some of the ablest men practicing the specialty of orthodontia today have never practiced general dentistry. I cannot consider my own ten years of dental practice otherwise than a severe handicap to attaining success in orthodontia.

Children who go to the specialist as frequently as they have to go to an orthodontist, for a period of years usually, become just as loyal and enthusiastic friends of the specialist as any general practitioner could wish. They often become attached to the specialist more than they do to the family dentist.

If the committee's idea of the natural evolution of a specialist is correct, then every dentist should first learn the jeweler's trade, the toolmaker's trade, engineering, medicine, surgery, and numerous other vocations that have a bearing on the profession.

The preparation for any specialty should be so broad and comprehensive that there would be no need to go through some other profession or business to reach it. The time ought not to be far distant when all the colleges preparing students for the medical and dental professions, or any of their specialties, will have the first two years in common, with

the last two given to the specialty they may select for their life-work.

Postgraduate instruction that aims only to "clear up some of the more perplexing phases of their work" is very superficial indeed to men in practice. What men need, who have decided to take up a specialty, is an intensive course in the foundation principles upon which that specialty rests. The little details and niceties are afterward easily added to such a foundation.

I am in full accord with the committee's intimation that the law should define the specialist and protect the public against those who are incompetent to practice it.

We cannot deny that there is a real "danger of specialization in its narrowing influence;" but in this case of orthodontia, its leader so fully realized this and impressed it so indelibly upon his students that they have not only made their influence felt in dentistry, but as a class they are above the average in broadmindedness. As a rule, the men who take up a specialty are men who are not satisfied with their knowledge or skill, and are willing to study and work to improve themselves. If they continue in that attitude, they cannot become narrow. The real student views the specialty as a constant incentive to broaden his knowledge along all lines and especially those of the collateral sciences.

Those who are eager to specialize because they think they will find an easy road to high fees and short hours are doomed to suffer a great disappointment. The men who have caught the real spirit of specialization find themselves with less leisure, not more. To be successful in any specialty demands constant application and study, not only of the development of the specialty itself, but of all the collateral arts and sciences which have a bearing upon it.

Dr. Daniel H. Squire, Buffalo. While the sense of this excellent report of Dr. Stillman's is rather fearful of the future standards of dentistry, and the underlying thought seems to be one of better service, it also describes a growing desire upon the part of the dental man for in-

tellectual advancement, which is most encouraging. There is a universal desire for greater efficiency in our treatment of patients, so that our relations with them may be one of thoughtful care, rather than one of an empirical nature.

The word "service" means the performance of *duty* in any occupation. It is of the greatest importance to understand the meaning of duty in order that we may render a worthy service. Education is the medium through which we appreciate the relationship of practitioner to patient, and the broader the foundation the higher the ideals, and then will come the full realization of duty.

I do not believe that the specialist who has a true sense of duty, and who has been well grounded in the fundamentals of dentistry, will ever become so absorbed in his special line of work that he will lose interest in the other branches of his profession. On the other hand, the young man who announces himself as a specialist for no other reason than that of not knowing any better, is not a serious menace to the profession or to the community in which he resides, at least for any length of time. When he was in college, he probably followed the motto: "Never study today what you can bluff tomorrow," and instant specialization after graduation is the natural outcome.

The only way in which to prevent the average young man from taking up a specialty before having had any experience in general practice is by increasing his knowledge. This is being accomplished in two ways; first, by raising the preliminary educational requirements, and second, by increasing the scope of the dental curriculum.

The preliminary educational requirement has undergone constant revision and extension, until now it consists of a full four-year course in a standard high school, the instruction including one year each of chemistry, physics, and biology. It is only a short step to a pre-academic requirement of one or two years of college work, and a little later the full arts course. This is none too great when we realize how diversified are the demands of our profession and how im-

portant are its teachings in the preservation of health.

It has been said that ninety per cent. of the college men who are engaged in this great war have been successful in whatever undertaking they have pursued, and it will be found equally true of the dental student, provided his mind has been well trained prior to entering upon the study of dentistry. This is a practical test of the value of academic training.

With regard to the dental curriculum, it is well known that, twenty years ago, dental instruction was not only inefficient in the teaching of operative and prosthetic dentistry, but extremely superficial in those fundamental subjects which are so essential for the development of the student mind. Dr. Stillman has enumerated the changes which have taken place since that time, and it is only necessary for me to emphasize the early conditions by alluding to a paper written by Dr. James Truman of Philadelphia, entitled "Wanted! a Pathological Sense." Dr. Truman appreciated the great need of a broader scope in dental training.

Today, in the four-year course of dental instruction, there is little choice between the first two years of medicine and those of dentistry. The advantages for clinical instruction have increased to such an extent that a dental student has every opportunity to familiarize himself with the various operations in dental practice. Many changes have been made toward increasing the effectiveness of the instruction. For instance, the treatment of root-canals and the extraction of teeth have been eliminated from the floor of the general infirmary, and the student is taught to do these operations under an environment of surgical cleanliness.

Objection has been made to the introduction of English composition and rhetoric into the present dental curriculum. If those persons who complain of this advancement in dentistry could have the opportunity of correcting student examination papers for one day only, they would become the strongest exponents of such a course. Encouragement of the student in speaking correctly and writing a paper in which the thoughts

are arranged in proper sequence, is one of the most helpful kinds of dental instruction. Even members of dental faculties need not be discouraged from taking such a course.

These days are days of service to our Maker, our country, and to future generations; and I thoroughly believe that one of the greatest benefits of this war will be to make the American people realize more than ever a keen sense of duty and the giving of a higher service, no matter what occupation may be. This realization of one's responsibilities will exert a wonderful influence toward a co-operative spirit between the teaching faculties and student bodies of dental colleges. There will be a greater desire for work upon the part of the student; he will feel that he is in college for a purpose, and that every moment is golden in his search for knowledge. The *personnel* of the dental faculties will change, and those who are left will assume a different attitude toward their duties; the lectures and clinics will be enriched through thoughtful preparation and study, rather than formulated while coming to the lecture hall. This change is already being felt, and dentistry is unfolding a glorious future.

The Correspondent, Dr. ARTHUR W. SMITH of Rochester, then presented his report.

[This report is printed in full at page 914 of this issue of the DENTAL COSMOS.]

DISCUSSION.

Dr. A. S. Walker, New York City. Your Correspondent is to be congratulated upon his choice of a subject, and upon the comprehensiveness of the questions propounded by him. It is regrettable, however, that these annual reports, which are always most timely and interesting, do not receive a larger percentage of responses from those honored by the request for an opinion.

The speaker, being in agreement with the general conclusions drawn by your Correspondent, will confine his discussion to the questions raised by the dissenters,

and to emphasizing the more vital points in the correspondence.

In a consideration of this subject it is essential to determine if the operation is within the scope of good surgical practice. The evidence submitted by your Correspondent, and the observations of unprejudiced students, strongly favor the affirmative.

Kells' objections are certainly unconvincing. Had he been more specific in setting forth his objections he might have escaped the suspicion of being swayed by prejudice. With Blum reporting 98 per cent., Thoma 95 per cent., Furnas 90 to 95 per cent., Brooks and Nodine 90 per cent., and Rhein 75 per cent. of successful apicoectomies, it would appear to be a satisfactory operation. However, if Kells' replantations are equally satisfactory there is apparently no good reason for his switching to the operation under discussion.

Grove is more specific, and questions if there is a normal regeneration of bone after these operations, basing his conjectures upon his observations. He tells us he does not believe that tissue attachment to the root-ends ever takes place, and that therefore these operations are failures. He also questions the value of roentgenographic evidence of these processes. If such evidence alone is unconvincing, why ignore the clinical history of cases of focal infection? There is abundant evidence of cures in these cases.

Considering the cause of failures, ordinarily they may be attributed to inoperable cases, faulty technique, and what is probably the most frequent cause—reinfection due to bad root-canal work. The importance of this phase of the operation cannot be overestimated; for in spite of the educational work that has been carried on during recent years, much bad root-canal work is still being done; and here let it be said again, that every step in the root-canal filling operation should be guarded with strictest aseptic precaution. It is hoped that in this connection some steps will be taken by the profession to adopt a standardized technique for this work.

Should the operation be done by the specialist or the general practitioner? If the services of a skilful specialist are available, the patient's interests demand that he should have the advantage of such services. While I agree with Dr. Howe that any dentist can perform the operation, it is true only in the sense that any dentist can extract teeth or correct a malocclusion. Apicoectomy is a very simple operation, and yet to secure the best results the operator should possess skill acquired by experience.

The question of equipment in a material sense is *nil*, since a few dollars will purchase all that is necessary.

The charge that the general practitioner is unaccustomed to operating under aseptic conditions, and therefore is not competent to perform these operations, is only too true. It is for the profession to attack this problem, and the speaker believes that a standardized technique for root-canal work should be the first to receive attention. Its application to other procedures will naturally follow.

Dr. L. A. Timerman, Fort Plain, N. Y. Our Correspondent has very carefully covered the ground of apicoectomy with his questionnaire. Not only carefully, but he has endeavored to bring out every phase relating to the operation. His whys have been insistent. This method with its brevity is to be greatly commended.

The resection of roots where pathologic conditions exist has passed the hysterical stage, and we no longer fear another "emetin" bugaboo, with its backlash.

Since it is definitely known that focal infections cause so many systemic disturbances, the dental profession has taken cognizance of the fact that it is in their field of operation, and are now looking forward to a standardized method for the operation.

Two very important questions at once arise: How and by whom are these operations to be performed? In following the summary of our Correspondent a very clear and comprehensive technique can be deduced. The fact that asepsis is known by all to be the important factor in surgery, our Correspondent has evi-

dently considered as axiomatic. But he recites in detail the tooth-roots most easily amputated, when and how the root-canal should be filled, the best method of removing the apex, and when suturing is preferable to packing.

However, the last question submitted by our Correspondent, "Should the operation be performed by the general practitioner or the specialist?" arrests our attention, and it should answer our second important query. Here the replies are greatly at variance, but the deduction from these replies was in favor of the specialist. As to the specialist's technique being superior, his skill developed to a greater efficiency, his equipment, both surgical and office, better adapted, his speed at operating being greater, and his knowledge of conditions that would contra-indicate operating, we most positively affirm.

No ulterior motives can be attributed to the authors advocating the specialist. No doubt they are all specialists. As we all do, they recognize exquisite skill, the result of practice, to be the great factor in getting results.

Today the highly specialized man is sought in every walk of life, and we unhesitatingly admit his *par excellence*. At the same time, the average dental surgeon who is strictly conscientious in his undertakings should not be discouraged in attempting this class of operations. In making this statement I am not considering the operator or the operation so much as I am certain classes of patients. Neither am I confining my arguments to this great state of ours, where transportation facilities are wonderful and specialists numerous, but am taking into view more remote sections.

This same opinion prevailed a few years since regarding orthodontia. Today we find thousands of irregularities corrected by the general practitioner in which patients directed to the specialist could not have availed themselves of the privilege, and would today be living monuments of shame to the profession. Radiography has been developed in the same manner, and no dental equipment is now complete without an X-ray outfit.

In his general conclusions our Correspondent says, "The majority of dentists consider apicoectomy advisable." He further concludes—and is fully justified by the replies—that "Unless the general practitioner is well equipped, has a thorough knowledge of asepsis, and has developed a skilful technique, the operation should be performed by the specialist." The sum total of the argument is this: Apicoectomy is advisable; if you are not a specialist, or cannot get your patient to a specialist, side-step; extract or let it remain a pathological tooth.

Every community distantly located from the centers of specialists has the right to expect the general practitioner, the dental surgeon, to be qualified to perform ordinary operations of orthodontia, apicoectomy, the treatment of pyorrhea, to be versed in radiography; and every man should qualify.

We have all been reading during the past three years the articles in our journals on war surgery of the jaws and face, of the septic conditions under which the wounds were caused, and the time which often elapsed before the first treatment. How do such operations compare with the resection of the apex of a root by an almost painless and bloodless operation—an operation requiring not more than a half-hour? Dr. Howe's statement read by our correspondent, "A simple thing; any dentist can do it," looks very reasonable. It is not a case of life or death, except to the tooth, and I do not know that the second state is worse than the first.

The upper anterior teeth most frequently claim the attention of the operator because of their prominence and accessibility. When all known methods of treatment fail and the specialist is beyond the reach of the patient, it is plainly the duty of the dentist in charge to apicoectomize the root. It is also his plain duty to perform that operation with the greatest possible precautions, antiseptically and surgically. The radiographing of the infected area is a necessary safeguard, and frequent films showing the progress of bone regeneration, if any, are reminders of the success or failure of

the operation and are of great value to the general practitioner who is making every possible endeavor to succeed.

It is not the intention to advocate that all operations about the mouth be done by general practitioners. But periapical infection is so common that the man who will bestir himself can soon acquire the necessary technique. It is for the benefit of such general practitioners that this subject is being discussed today, but the greatest benefit will be received by our clients, for whom I am making this plea.

Dr. L. L. Mulcahy, Batavia. We have listened to a most complete report on the subject of apicoectomy, compiled at the expense of considerable time and labor by our Correspondent, Dr. Smith, who deserves much credit for the excellent manner in which he has presented it to us.

This report was compiled from replies received from experts on the subject. You have heard it discussed by men who have had considerable experience in amputation of root-ends, and know what they are talking about. In selecting me to discuss this report, I presume the idea was to select a general practitioner who knows very little, if anything, about apicoectomy, to see what we think about performing this operation.

I was glad to hear Dr. Stillman say that we should broaden and spread out. I am one of those located in a city too small for specialists, where, if you wish to render the best service to your patients, it behooves you to specialize in all the various branches. One of the things I have taken up is radiography, which I think is essential to intelligent root-canal work, and to apicoectomy.

I believe that the average general practitioner who will equip himself with an X-ray machine, sterilizing outfit, proper instruments, and a good assistant, can successfully take care of the simple cases. By these I mean the ones most accessible and where the area involved is not large, assuming that the root-canal has been properly filled.

For the general practitioner I shall outline a little technique. Ten or twelve years ago I attempted to do this in a more or less haphazard way, but of late, I am glad to say, I have been quite successful with the method I have adopted.

I prefer novocain anesthesia. I have tried nitrous oxid, but have not been successful. I first make a long incision, retract the flap toward the lips, using sharp burs, and normal saline solution for irrigating. I have always packed the wound lightly with iodoform gauze instead of suturing, but in many of the simple cases, where the incision is not large, I believe suturing would be preferable, as I have had some post-operative pains, and that would do away with them.

I believe we should be prepared to take care of all these simple cases where we are not accessible to the specialist, and advise our patients to submit to the operation, especially in cases where a front tooth is involved, as in my opinion an apicoectomized tooth is preferable to a bridge. If you have a tooth, however, where the risk is too great, it is better that a specialist should treat the case.

Adjournment to 8 P.M.

(To be continued.)

Eastern Association of Graduates of the Angle School of Orthodontia.

Ninth Annual Meeting, held in New York City, May 6 and 7, 1918.

THE ninth annual meeting of the Eastern Association of Graduates of the Angle School of Orthodontia was held on Monday and Tuesday, May 6 and 7, 1918, at the Vanderbilt Hotel, New York City.

MONDAY—*Morning Session.*

The meeting was called to order by the president, Dr. Frederic T. Murlless, Jr., of Hartford, Conn., at 10.30 o'clock.

In the absence of the vice-president, ex-President H. C. Ferris of New York occupied the chair while President Murlless read his address, as follows:

President's Address.

By FREDERIC T. MURLESS, JR.,
Hartford, Conn.

Ladies and gentlemen,—We are gathered again in this familiar place for our ninth annual meeting, and it is a pleasure to be permitted to extend to all a hearty welcome. It is sincerely hoped that the program which has been arranged will prove as great a source of pleasure and profit to you as its preparation has been to your officers, to whom as president I wish to express my appreciation of their support and co-operation.

In reflecting upon the interests of this association, it has occurred to me that the history of all the arts and sciences is much the same, in that their beginnings have all been within the range of the obvious, while all alike have suffered from too swift and sweeping generalizations based upon a degree of success measurable only in terms of inexperience. With experience and experiment as teachers, progress has always been

problematical, and the dissemination of the slowly accruing knowledge has been restricted and obstructed by the personal limitations and antagonisms of men who often have had little to impart.

The age of empiricism as a stage of adolescence is interesting historically, though trying as an experience, and survival of this stage is a dependable index of the vitality and permanence of every science. Resourcelessness in the solution of oft-recurring problems by means of mere experience must lead to study in allied lines of thought, and has been the spur to effort and development in individuals, and their final grouping in recognition of mutual purpose.

The dominance of theory as the moving force, and practice as the proof, marks the establishment of each science, or branch of professional endeavor, as an independent organism. To this stage Orthodontia has long since arrived, but it is a notable fact that the initial impulse of the past has so survived as to be recognizable as the binding and directing force in this association.

It is ground for legitimate pride, in which every member of this association may well participate, that our active interests as a body extend to the allied fields of child hygiene, the pathology of the digestive tract, biology, anthropology, orthopedics, the study of the ductless glands, heredity, comparative anatomy, art, engineering, etc., as well as to the more immediate interests such as etiology, anatomy, and metallurgy. It need but be said that in all these various fields this association has a vital interest, and in many of these there has already been done work of constructive value by its

members. We are each year making fresh discoveries in the common ground which lies between us and many of the older sciences, the cultivation of which produces fruit for the labors of both, and profit for each.

With so remarkable and creditable a record already made, it should not be forgotten that no small responsibility rests upon this association as builders of a great science which has to do with the correction and prevention of the most prevalent deformity known to the human race.

By way of recommendations and suggestions for the future, your president asks your attention to a few items pertinent to our progress, and with the purpose of widening the influence of this association.

First: That in order that the officers may be unhampered in the management of the affairs of the association, the dues should be increased to five dollars per annum.

Second: That orthodontia may in the future be held in the keeping of educated men of the highest type, that this association appoint a committee to inquire into and recommend a plan for establishing a scholarship of such character as to attract and develop men qualified to become leaders in our specialty.

Third: That consideration be given to the standardization of X-ray procedure, for the purpose of eliminating the variations in electrical potential distance, angles, and position of films, and increasing the value of comparison of consecutive skiagraphs of the same area.

Fourth: That the incoming president appoint a committee on the sequences of orthodontic procedure.

In conclusion, permit me to express the hope that the ever-widening sphere of influence of this association may continue to be the inspiration of its members, and to thank you for the great pleasure and honor that it has been to me to serve as your president.

DISCUSSION.

Dr. H. E. Kelsey, Baltimore, Md.
I am heartily in favor of raising the dues

to five dollars. It has always seemed to me that three dollars was rather an inadequate amount of dues to properly conduct our society, and I agree with the president that it would be a very good thing to increase the dues. I very much enjoyed the address, and I believe the recommendations in it if carried out will be of great value.

Dr. R. B. Stanley, New York. It is a time-honored custom that at the opening of a meeting like this we listen to the reading of the President's Address, and I think it is a most wholesome one. It gives us an opportunity to think over those things that have been done, and also those things which we have not done, and it gives us a few moments for reflection in which to make resolutions for the future.

In our meetings during the year that has just closed we have had in our program a great deal of constructive material, and President Murlless has pointed out the way in which we can continue that work. I have noted with much satisfaction, in talking with the men at the meetings, that underlying all this has been a spirit of good-fellowship. I do not mean the good-fellowship that is just a clasp of the hand between two men of the society; but I mean the fellowship that urges you to get out and know the world as it is. This is probably the largest society of its kind that meets regularly for this kind of work. Perhaps you do not realize that. If we want to progress, we need to get out in the world and to know the members of the dental profession, and the members of the medical profession as well. I think this is a proper time for us all to resolve that the spirit that has been shown in the past will continue, so that everyone will feel he is welcome to come to these meetings. I, for one, intend to do that, and I hope all the rest of you will do the same.

Dr. G. W. Grieve, Toronto, Canada.
I thought it might not be out of place to mention a thought that has come to me in teaching orthodontia, and any of you who have had experience in teaching this branch in the dental schools must

have had some of the same difficulties that I have had. It might be an advantage if a committee were formed with the object of determining a definite course of instruction in orthodontia, and its limitations. I simply offer that suggestion to bring out the thought of the members as to whether we should not all get along better if we could decide upon a definite course in orthodontia in dental schools.

Dr. B. W. Weinberger, New York. There is one point in the President's Address, as to the formation of a certain committee—that was one suggestion I did not quite comprehend. I think it would be an opportune time for us to have a committee appointed to arrange for a uniform examination blank or report to be used by all our members, so that when we wanted information we could call on the different members, and get reports of cases that would be uniform. We all have our own ideas, and if there is anything perplexing, something that we would want to consult one another about, each one's records would be valuable to the other. If that is not what the president meant, perhaps that could be included in the recommendations of the Committee on the President's Address.

The President. Perhaps a word of explanation in regard to that paragraph would make my meaning clearer. I will read it again: "That the incoming president appoint a committee on the sequences of orthodontic procedure."

My idea is this: We have had various groupings of orthodontic cases. The major and important grouping, as a starter at any rate, was Angle's classification. But no two cases are alike, and many cases that are doubtfully in the same Angle classification require different treatment, and allow wide latitude for the personal element. I think it would be helpful, not only to the man who has some good reasoning in regard to his attitude—not only to him, because of the benefit of telling it and broadening his own ideas, but also to those who have perhaps not run across such a case, or had such an unfortunate experience

as to find their attitude was not quite correct, and who might be saved from unnecessary difficulties.

I know that many referred cases are a bugaboo to many men, and for the reason that there is no real reasoned conclusion for an accepted attitude toward any particular case; and yet there must be a right way, still allowing for the personal element.

In regard to the matter of the scholarship, my idea was, in a word, that a committee might take up the question from the attitude of the Rhodes scholarship. There is no reason why our profession should not be drawing on the potentialities of riper men than we, men created by this age by their opportunities to be bigger than we. Other branches of endeavor are producing them, and it would not be at all out of place for us to produce a few ourselves. The Eastern Alumni Association of Angle Graduates consists of men who are known no longer as boys; and yet the burden of this work rests upon us. Dr. Stanley was right about it. We have a big responsibility, and we should make sure that what we sow falls on good ground.

It seems to me as though we were really at this time the only group of men upon whom this duty falls.

Dr. Wm. G. Law, New York. I enjoyed the President's Address immensely, and I think I agree with everything he said. I would even be in favor of raising the dues much higher. It occurs to me that we could readily pay an amount which would enable the society to apply a portion of it to such a worthy thing as a fellowship or scholarship.

I am quite in accord with everything the president has said.

Dr. A. W. Crosby, New Haven, Conn. I move that a committee of three be appointed to consider the recommendations contained in the President's Address, and make a report thereon to the society later in the meeting.

The motion was carried.

The chairman appointed the following as the Committee on President's Address: A. W. Crosby, New Haven; H. E.

Kelsey, Baltimore; J. V. Mershon, Philadelphia.

President Murlless then resumed the chair, and a short recess was taken.

The President again called the meeting to order, and introduced Dr. HOWARD T. STEWART of New York City, who spoke on the following subject, "Restoring Missing Teeth after Orthodontic Procedures; and Thoughts on Moving Teeth Loosened by Riggs' Disease," illustrated by lantern slides.

[This paper will be published in a later issue of the DENTAL COSMOS.—ED.]

MONDAY—Afternoon Session.

The meeting was called to order at 2.30 o'clock, by the president, Dr. F. T. Murlless, Jr.

Mr. LESLIE SPIER, of the American Museum of Natural History, gave a lecture on "Physiological Age: The Relation of Dentition to Body Growth."

[This paper is printed in full at page 899 of the present issue of the DENTAL COSMOS.]

DISCUSSION.

Dr. H. C. Ferris, New York. We are all interested in assisting Mr. Spier in collecting this data, which would be of such practical value to the profession, and if each member would give ten or more records I believe that would start the ball rolling. Efforts along this line have been made in our society before, but owing to the time required to collect the data, few of our members have complied, and the effort has proved to be more or less a failure. I make this as a motion: That those of us who feel able and willing should raise our hands and agree to furnish Mr. Spier with such data as he may wish for ten cases of adolescence, so that he may have some basis for continuing his work.

Mr. Spier. Data are not hard to obtain. I do not want a great deal—I am trying to place things before you in the easiest way. I simply say, "Let me see your records." When you get a case and

prepare to take the ordinary record, ask the patient to step on the scale, and pull the stature bar over his head, and you have at once two more indices to help us and yourselves; for often those two indices will give you a pretty good insight of what you may expect that dentition to be like. This data will not be packed away in big fat tomes and allowed to get dusty, but will be of use to all of us. I ask that you be good enough to allow me—or someone who is interested as I am—to see your data. This can be done with the least inconvenience to you, I am sure. As for those who are out of the city and not available, I shall be pleased to have whatever you send. Ten cases each from 35 men would be a series of 350. That would be a very small series. Let me have all you can. If you can give me fifty without encumbering your secretaries, let me have them.

Dr. J. Lowe Young, New York. As I understand it, in addition to the age, weight, and height, Mr. Spier wants the time at which certain teeth erupt.

Mr. Spier. The better way would be to record the exact time at which the tooth erupts, by whatever criterion you reckon it. If you tell me you have a boy of ten years with such and such teeth, I could calculate at what time he must have erupted his teeth, if he is an average individual.

Dr. Young. From my own records, I would not be able to give the exact time at which the teeth erupt. While I could not do that with my past cases, it would not be much of an effort to do it with present or new cases. I did weigh and measure some of my patients, but for another purpose, and I do not know now what became of the records.

Dr. Milo Hellman, New York. Ten cases would be very little; you can easily get three times that many by following a certain scheme. What Mr. Spier wants is what you already have in your possession. The age, weight, and height you can easily take. You have the casts at the age at which the patient came to you. If we in New York, or within easy access of New York, would grant Mr. Spier permission to look at our records,

we would not have to describe the cases. Just show him the record, and he will do the rest. He is interested in the mouth at the age at which it came to you, and not in the outcome. All that is necessary is to accord him the privilege of having free access to our collections of models, and furnish him with the data of age, height, and weight. That would be sufficient to assist him to establish quite a series of records.

Dr. Ferris' motion was carried.

Dr. F. L. Stanton, New York. I would like to move that a committee be appointed to standardize the record forms so they may be easily distributed, and the data be gotten in proper form.

Dr. Bernard Weinberger, New York. That was what I referred to when I discussed the President's Address this morning. We should cover not only this field, but take men like Hrdlicka; or Mr. Sullivan or some of those other men at the museum, and see if we cannot get the records broad enough to cover all they want, because there are other questions they are investigating at the same time.

Dr. Stanton's motion was carried.

The President. We all deeply appreciate the courtesy and the point of view of Mr. Spier in bringing this matter to us, and realize it is a labor of love, as our activity in regard to this subject must needs be, and we have a fellow-feeling for him.

A vote of thanks was tendered to Mr. Spier.

Dr. ALFRED P. ROGERS of Boston, Mass., then read a paper entitled "Exercises for the Development of the Muscles of the Face, with a View to Increasing their Functional Activity."

[This paper is printed in full at page 857 of the present issue of the DENTAL COSMOS.]

DISCUSSION.

Dr. A. L. Johnson, Springfield, Mass. Does Dr. Rogers find it advisable to use the whole system of exercise in all cases?

Dr. Rogers. No. In class II the pterygoid and posture exercises; in class I the exercises for the general development of the face; in class III the muscles worked in the opposite direction. The entire system is an effort of the will, and it is a wonderful help if you can coordinate the mind and the muscle. We know of the athlete who can control any set of muscles at will. Anyone who undertakes this kind of work should be able to perform the exercise himself. There is not a thing I have taught my patients to do that I cannot do myself, and I do not attempt to instruct a patient in any exercise unless I know I can do it myself.

Dr. Julius Minez, Newark, N. J. What success has Dr. Rogers had with the short upper lip in class II cases?

Dr. Rogers. The lip can be changed in shape. One of those cases, which I referred to as a persistent mouth-breather, is showing a great deal of improvement in lip form. It is not so much a short upper lip as the contour of the mouth in general, and its habits.

Dr. C. A. Hawley, Washington, D. C. I have seldom listened to a paper that shows as much good sense and careful observation and experience as this one. It occurs to me that it affords practically the only solution of the retention problem. It refers to what I think we all believe is the etiology of malocclusion, the lack of function, that is, in the majority of cases. Unless in the end, after our mechanical work, we can restore something near the normal function of the teeth and the muscles surrounding them, retention is almost hopeless. We have all had cases, and it is unnecessary to go over them, where mechanical retention has failed. They recur again and again, and there is no time when we can remove the retention and say the case is finished and the teeth will stay.

I have had no experience whatever in these exercises, so I cannot discuss the paper in detail. It has often occurred to me that it is possible to change the food habits of people in our civilized state. I think I referred to that in an address about 1908. If we can change

the food habits of the child and aid it by these muscle exercises, I think there is hope, and the results Dr. Rogers has had are, to say the least, extremely encouraging.

There is another tendency shown in Dr. Rogers' work which is extremely gratifying, and conforms to my later experience, and that is, the tendency toward simpler appliances. The whole paper impresses me more than anything I have heard in a long time. It is along lines that are going to be more and more successful in the future.

Dr. H. E. Kelsey, Baltimore, Md. I do not think I have sufficient experience along these lines to discuss the paper, but I cannot let the occasion go by without expressing my appreciation and obligation to Dr. Rogers. I believe this paper marks an epoch in orthodontia. A man I had not seen for some years said to me this morning that he did not know what orthodontists needed, but he said we needed something. We need this; it may not be all we need, but it is a great step in the right direction. The great change in the faces Dr. Rogers showed us was more significant and pronounced than anything I have seen in any similar cases. It is not alone that the protrusions were corrected and the profile was improved, but it seemed that almost every bone in the face had been altered, and strengthening harmony given to the whole head.

As Dr. Hawley has said, we have had cases where retention seemed hopeless, and we have had other cases where we thought we secured wonderful results, estimating exactly the time at which we could take our retention off. Those were undoubtedly the cases where function was fully restored. Those where the retention fails are those in which the function has not been restored. I know of no paper that has stimulated me so much, for a long time, as this one by Dr. Rogers.

Dr. A. Leroy Johnson, Springfield, Mass. I believe that Dr. Rogers' paper is a distinct contribution to a real science of orthodontia. An orthodontia which concerns itself with nothing more than the mere movement of the teeth, by

means of appliances cemented to them, has not much of an excuse for being. There is one thing that occurred to me during the reading of the paper, that is, the necessity of evolving scientific tests to distinguish definitely the different natures of these cases; also the need of instruments which will indicate progress made in the training the essayist has outlined in his paper.

Dr. H. C. Ferris, New York. I want to compliment Dr. Rogers on the beautiful presentation of this scientific subject. A few years ago I presented to you a little rubber exerciser, and it was generally scoffed at, and very little attention was given to what was termed a "rubber rope." With that rubber exerciser I have been accomplishing the development of the muscles of the face and mastication by systematic exercises. In class II cases I instruct the child to roll forward on the rubber rope, and in class III to roll backward and bite as hard as possible a definite number of times at regular intervals on teeth which are under orthodontic pressure. For the orbicularis oris I have the child learn to whistle, and keep the fingers out of the mouth, as I found that a dangerous practice. Dr. Rogers has anticipated a report of my work, but has done the subject justice, and I congratulate him.

In reference to Dr. Hawley's idea of dietetics, I want to predict that the question of salivary analysis will eventually direct the dietetics of our patients. Through this means I am directing the diet and controlling the general physical condition of my patients in sustaining the tone of the alimentary canal and eliminating many of its acute and chronic diseases.

I am delighted to have heard this paper, and I hope it will have far-reaching influence.

Dr. G. W. Grieve, Toronto, Canada. I would like to add my word of commendation to the paper Dr. Rogers presented. One phase of it pleased me particularly, and that was the exercises which would tone the orbicularis oris muscle. We have all seen many patients with that terribly inert condition of that muscle

which almost makes us decline to attempt to treat the case. That particular point was very pleasing to me, and I am much encouraged now to take on those cases that I did not like the appearance of before.

Dr. J. V. Mershon, Philadelphia, Pa. I cannot let this occasion go by without expressing my appreciation of the work of Dr. Rogers. I hope he will carry it farther. I am reminded of a few records I have made in my own cases of the connection between mal-development of the bones of the face, which is sufficient to produce malocclusion, and the general mal-development of the whole child. I have made this statement on other occasions, and think if the men of this organization were to make a careful analysis of their patients, and obtain the history of their cases, they would find that where there is malocclusion to any extent we have many defects in the muscles and bones in the other parts of the body. I was hoping Dr. Rogers, in closing his paper, would express his conclusion a little differently; that he would have said orthodontia not only embraces the moving of the teeth in their relative relations to each other, but that all the organs and all the tissues of the mouth must be restored to their normal function.

Another important item which Dr. Rogers touched on, but with which he did not go quite as far as I would have liked to see him, was in expressing himself in regard to the various appliances. We have a large variety of appliances which are now in general use, but I think

the ideal appliance is one which interferes the least with the normal functions of the tissues and organs of the mouth.

Dr. J. A. Gorman, New Orleans, La. Dr. Rogers has given us something that will doubtless fill a long-felt want. I should like to see him perform those exercises for us, so that we could get a better idea of the movements of the muscles, especially in the exercise of the orbicularis oris.

The President. I had a sort of kindergarten course with Dr. Rogers about a month ago, which rather opened my eyes. In fact, I was rather stunned at the scope it presented to my mind at the time. I think perhaps Dr. Rogers felt I was not as enthusiastic as he would have wished, but I have thought of it a good deal since that time, and have been ready for another step in this matter. I have enjoyed the paper today, even more than the rest of you, I am sure, unless you have had the privilege of hearing this matter spoken of before.

Dr. Rogers (closing the discussion). I want to thank you all for the very kind way in which you have received my paper. There is much more that I might tell you, but I do not want to speak too soon. I want to be positive of the things I do for my own patients. There will be more interesting results to come later.

The meeting then adjourned to 10 o'clock Tuesday morning, the Monday evening session being devoted to an informal dinner for the members and their guests, including the ladies.

(To be continued.)

THE DENTAL COSMOS

A MONTHLY RECORD OF DENTAL SCIENCE.

Devoted to the Interests of the Profession.

Subscriptions and communications relating to advertisements should be addressed to the BUSINESS MANAGER of the DENTAL COSMOS, Lock Box 1615, Philadelphia, Pa.

PHILADELPHIA, OCTOBER 1918.

EDITORIAL DEPARTMENT

Expansion of the Army Dental Corps.

WHEN the United States entered the European conflict the apportionment of dental surgeons provided by law was one-tenth of 1 per cent. of the army *personnel*, or one dental surgeon to each thousand men. To all who were cognizant of the facts of the situation it was clearly evident that the allotment of dental surgeons was totally inadequate for the effective care of the dental needs of the army. Basing the working capacity of a dental operator on a total of two thousand hours per year, which is a liberal estimate, and leaving no margin for loss of time, if his service were equally apportioned it would make an average of two hours annually available for each of the one thousand men under his care. Two hours per year per man is wholly insufficient for the proper care of his dental organs, and realizing that fact the dental committee of the Medical Board, Council of National Defense, took active steps toward providing a more efficient army dental service by recommending an increase in the *personnel* of the Dental Sur-

geons Corps. The seed thus sown has at last borne fruit, for announcement has just been made of an authorized increase of 100 per cent. in the *personnel* of the corps, so that the new ratio will be one dental surgeon to each 500 of the army *personnel*, with three dentists to each base hospital.

We are informed that 8981 commissioned dental surgeons plus 10 per cent. for replacement will be required for active service by July 1st of next year. There are at present in round numbers 3500 dental surgeons on duty, with 2500 on the reserve inactive list, and of these latter it is probable that at least 1000 will be called to active duty. The 5500 additional dental surgeons needed to make up the quota of 10,000 required by next July will be made up by new commissions, of which it is estimated that 2500 will be obtained from conscripted dentists now in the ranks, leaving from 2000 to 3000 to be obtained from other sources.

The effects of this extensive expansion of the Army Dental Surgeons Corps will be fundamental and far-reaching. The most important and basic consideration is the benefit which is wrought by this enlargement in the *personnel* to the morale of the corps itself. There can hardly be any factor which exerts a more demoralizing influence on the character of an individual than to place him in a position where he is expected to produce results that he knows to be, in the nature of the circumstances, impossible of accomplishment. It is precisely that kind of situation in which the army dental surgeon has been placed when he has been required to look after the dental needs of 1000 men—a task which no one can do properly, and involving the inevitable result that it is done improperly, or to a considerable degree it is not done at all; there is no other alternative. The result so far as the dental care of our soldiers is concerned is obviously that they could not receive the full measure of dental attention they require, for which reason, though valuable as far as it went, the army dental service under the old apportionment necessarily fell far short of what it could be and should be. The new allotment will go far toward correcting these fundamental evils, and will place dental service in the army in a position where it can practically demonstrate its value and importance in maintaining the physical efficiency of our fighting men.

Another important result of the new order will be its reflex

effect upon dental educational activities in the immediate future. It is highly questionable whether the large additional number of army dental surgeons required by July next can all be drawn from the body of dental surgeons now in civil life. A fair proportion will be needed to care for the needs of the civilian population, and there are even now no more than a sufficient number for that purpose. The main reliance of the Government will therefore have to be upon the classes that will graduate at the close of the current session of the dental schools. And in order to secure a sufficient body of graduates to meet both army and civilian needs it seems inevitable that a considerable body of students will have to be recruited from the present draft quota and assigned to dental educational institutions, under army regulations, to pursue the dental course.

Such a correlation of military training and dental education under government regulation has much to recommend it as a disciplinary system both for the mind and for the body. Not the least of its advantages will be the opportunity that it will afford to substitute something really useful in the dental curriculum for that academic mongrel called "dental rhetoric," whatever that may be, which someone has apparently succeeded in impinging upon the standardized dental curriculum recently authorized by the Dental Educational Council of America.

We have endeavored herein to present merely the main elements of this important development, and will keep our readers informed regarding the detailed changes and regulations as they arise from the practical applications which the new order will necessarily involve.

Classification of Dental Schools.

THE following is the formal classification of dental schools as adopted by the Dental Educational Council of America, at Chicago, Ill., July 31, 1918:

Class A.

Creighton University, College of Dentistry, Omaha, Nebraska.

Harvard Dental School, Boston, Mass.

Marquette University, College of Dentistry, Milwaukee, Wis.

Medical College of Virginia, School of Dentistry, Richmond, Va.

North Pacific Dental College, Portland, Oregon.
 Ohio State University, College of Dentistry, Columbus, Ohio.
 The Thomas W. Evans Museum and Dental Institute, University of
 Pennsylvania.
 Tufts Dental College, Boston, Mass.
 University of California, College of Dentistry, San Francisco, Cal.
 University of Illinois, College of Dentistry, Chicago, Ill.
 University of Iowa, College of Dentistry, Iowa City, Iowa.
 University of Michigan, College of Dentistry, Ann Arbor, Mich.
 University of Minnesota, College of Dentistry, Minneapolis, Minn.
 University of Pittsburgh, College of Dentistry, Pittsburgh, Pa.
 University of Southern California, College of Dentistry, Los Angeles.
 Northwestern University, Dental School, Chicago, Ill.

Class B.

Colorado College of Dental Surgery, Denver, Colo.
 Georgetown University, School of Dentistry, Washington, D. C.
 Howard University, Dental School, Washington, D. C.
 Atlanta-Southern Dental College, Atlanta, Georgia.
 Louisville University, College of Dentistry, Louisville, Ky.
 Chicago College of Dental Surgery, Chicago, Ill.
 Indiana Dental College, Indianapolis, Indiana.
 Loyola University, School of Dentistry, New Orleans, La.
 Tulane University, School of Dentistry, New Orleans, La.
 Baltimore College of Dental Surgery, Baltimore, Md.
 University of Maryland, Dental Department, Baltimore, Md.
 St. Louis University, College of Dentistry, St. Louis, Mo.
 Washington University, Dental School, St. Louis, Mo.
 Kansas City Dental College, Kansas City, Mo.
 Western Dental College, Kansas City, Mo.
 University of Buffalo, Dental Department, Buffalo, N. Y.
 New York College of Dentistry, New York.
 College of Dental and Oral Surgery of New York.
 Western Reserve University, Dental School, Cleveland, Ohio.
 Ohio College of Dental Surgery, Cincinnati, Ohio.
 Philadelphia Dental College, Philadelphia, Pa.
 Vanderbilt University, School of Dentistry, Nashville, Tenn.
 University of Tennessee, College of Dentistry, Memphis, Tenn.
 Meharry Dental College, Nashville, Tenn.
 George Washington University, Dental School, Washington, D. C.
 College of Physicians and Surgeons, Dental Dept., San Francisco, Cal.
 Baylor University, Dental Department, Dallas, Texas.

Class C.

Lincoln Dental College, Lincoln, Nebraska.
 College of Jersey City, N. J.
 Cincinnati College of Dental Surgery, Cincinnati, Ohio.
 Texas Dental College, Houston, Texas.

PRACTICAL HINTS

This Department specially welcomes the brief presentation by our readers of any novel suggestions or methods which in their own practice have proved to be time-saving or to possess other features of advantage.

Vulcolox Anteriors in the Construction of Richmond Crowns and Bridge Work.

By ADOLPH GROPPER, Milwaukee, Wis.

THE pin in the tooth is first given a one-half turn with narrow-beaked pliers so as to bring the longest line of the oblong head of the pin to a right angle with the long axis of the tooth, as shown in Fig. 1.

FIG. 1.

A piece of clasp-metal plate, 28 gage, is cut to the shape shown in Fig. 2; a slot is then cut in the center of one side as indicated, to engage the pin in the tooth. This clasp-metal plate is held with narrow-beaked pliers, and both ex-

the extending wings of the dovetail fitting, Fig. 3.

The dovetail fitting, Fig. 3, is then adjusted into the slot of the tooth; the

FIG. 4.

FIG. 5.

backing, Fig. 4, is burnished to place, and waxed to the dovetail fitting, Fig. 5. Remove, invest, and solder.

FIG. 6.

FIG. 7.

tending ends are bent so as to closely fit the three-sided dovetail slot in the tooth, Fig. 3.

Backing material is burnished to the back of the tooth, extending to its gingival labial edge, and two slots are cut through the backing, Fig. 4, to receive

The backing is next adjusted and waxed to the cap as shown in Fig. 6, and soldered in the usual manner, completing the crown, Fig. 7.

REVIEW OF CURRENT DENTAL LITERATURE

[*Lancet*, London, July 6, 1918.]

Operative Treatment of Trigeminal Neuralgia. BY J. HUTCHINSON.

This article is of great interest in connection with that of Frazier (*Jl. A. M. A.*, May 11, 1918, and *DENTAL COSMOS*, September 1918, p. 829). Both surgeons agree that the only treatment affording lasting cure is an operation on the Gasserian ganglion. Hutchinson believes that the method of Frazier and Spiller (division of sensory root) is too hazardous and uncertain ever to come into favor; and moreover, it has the disadvantage of destroying the ophthalmic division. Primarily it is to save this division that Hutchinson devised his method. This is not only urgently desirable but is quite feasible, because in only 25 per cent. of cases of trigeminal neuralgia is the ophthalmic division materially involved.

The ganglion is removed by three lines of section: (1) Division of the inferior maxillary division at the foramen ovale; (2) division of the superior maxillary division at the foramen rotundum; and (3) a horizontal cut below the ophthalmic division, which is thus spared.

Of over sixty cases operated upon, only one has proved fatal, and in this the patient was a very bad risk. After removal of the ganglion, Hutchinson has followed up many cases for over ten years, some for nearly twenty years, and the neuralgia has not returned. This statement is true of the great majority, but there have been a few exceptions, difficult to explain. In only one case has the neuralgia returned—to be localized in the ophthalmic division, some ten years after operation. In this case resection of the supra-orbital nerve was a complete success for the period of observation (three years).

The complications sequent to Hutchinson's method are no other than those liable in any

other operations. The results are among the most satisfactory of any the surgeon will encounter.

Hutchinson is very emphatic that *the extraction of teeth with the view of relieving or curing true epileptiform neuralgia is a pernicious and useless practice*. There exists in his opinion no valid evidence to regard trigeminal neuralgia as a spreading neuritis of dental origin.

In respect to alcohol injection, either of branches of the fifth nerve or into the foramen ovale and its neighborhood, Hutchinson is quite in accord with Frazier. To them it is but an indifferent substitute for operation on the Gasserian ganglion. Ocular and aural complications may result from alcoholic injection.

Cheatle (*Lancet*, London, July 13, 1918, p. 56) has seen two cases in which the middle ear has been badly and permanently disorganized, owing apparently to the alcohol entering the Eustachian tube.

[*Journal of Infectious Diseases*, Chicago, June 1918.]

Streptothrix Interproximalis—nova sp.: An Obligate Micro-aerophile from the Human Mouth. BY ERIC A. FENNEL.

The mouths from which this organism was isolated would be classed as "habitually unclean mouths with incipient caries and a liberal deposit of salivary calculus." The culture medium used was Martin's agar and aseptic fluid, on which macroscopically visible colonies developed in four or five days. Cultivation was conducted under the system of partial oxygen tension of Wherry and Oliver.

The organism is highly pleomorphic, growing in plaque-like colonies of intertwined and matted threads. Its morphology varies rather consistently with the age of culture. It stains with the ordinary dyes. A majority of the threads are Gram-positive. It is non-motile;

optimum temperature 35° C.; it does not grow at all at 20° C. or under anaerobic conditions, and only with the greatest difficulty aerobically. It produces neither pigment nor endospores.

Fennel details the cultural characteristics at some length.

[*Le Progrès Médical*, Paris, May 18, 1918.]

Frequency of Vincent's Angina. BY J. CHALIER.

Before the war 2.26 per cent. of all cases of angina were due to Vincent's organisms. For twenty-two months Chaliér was associated with the medical service to 2500 men. In his experience, there occurred 46 cases of true angina, 13 (*i.e.* 28.26 per cent.) of which were of Vincent's type. In the latter months of his service, there was a marked increase in the incidence of the disease.

On account of the possibility of contagion, it is advisable to isolate the patients for ten days. In from eight to twelve days, in cases receiving early treatment, cure has been complete. Successful results have been obtained from thorough washing out of the throat three times a day with 2 liters of boiled water to which a little H₂O₂ has been added. This is followed by a liberal application of powdered methylene blue to the craters of the ulcers.

T. J. Gallaher (*Laryngoscope*, St. Louis, July 1918, p. 551) has for a number of years been very successful in the treatment of Vincent's angina with trichloroacetic acid. The pure liquid acid, after excess has been absorbed on an ordinary blotter, is applied carefully to the entire affected area by means of a small applicator wound with cotton. The parts turn white in two to three minutes. Then neutralize by applying a saturated solution of sodium bicarbonate. Repeat in two or three days if necessary. It is rarely necessary to make more than two applications.

[*Surgical Clinics of Chicago*, Philadelphia, June 1918.]

Tumor of the Gasserian Ganglion. BY NELSON M. PERCY.

This is a case history with commentary. The patient was a male, age thirty-one years; family and personal histories negative. Complained of pain in right forehead, right ear, and right side of the face, beginning about

two years before being seen by Percy. Simple tic douloureux was eliminated because of the paralysis of the seventh cranial nerve; also because the pain became continuous soon after the beginning of the trouble and has persisted since, while in tic douloureux the pain is never so persistent, but is intermittent—in spasms. A probable diagnosis of tumor of the Gasserian ganglion was made.

The surgical technique of the removal of the tumor is detailed. The growth was 3.5 x 2.5 x 1. mm., was closely connected with and apparently included the ganglion. The nature of the growth is still in doubt. Diagnoses suggested by different pathologists were neurofibroma, fibrosarcoma, and endothelioma.

Convalescence was rapid and uneventful. The pain had stopped. The patient had not been seen since leaving the hospital.

[*American Journal of Syphilis*, St. Louis, April 1918.]

Leukoplakia of the Tongue. BY DOUGLASS W. MONTGOMERY.

The case reported is of interest for several reasons: Because of its occurrence in a young man (age twenty-two years), because of its association with syphilis (contracted at the age of sixteen years), and because it almost entirely cleared up under the use of radium and anti-syphilitic treatment.

The patient denied the use of tobacco at any time or in any form. This is important, considering the usually and undoubtedly justly accepted view that one of the chief causes of leukoplakia is tobacco smoke.

The radium treatment was as follows: A dime-sized plaque containing 24.23 mg. of radium element, and screened with A 1.005, cotton, and rubber, was applied for ten minutes, and reapplied in ten days. Two days after this last application a rather severe and quite painful reaction was obtained. In two weeks the hyperkeratosis had entirely disappeared, leaving what appeared to be a slight scar.

The syphilis was treated with salvarsan intravenously and with intramuscular injections of gray oil. This extended over a period of ninety-five days. The tongue condition never entirely cleared up; there remained the opalescent haze and decided local sensitiveness.

[*Medical Record*, New York City, August 24, 1918.]

Relationship of Oral Sepsis to Systemic Disease, and Its Bearing on Treatment.

By H. B. ANDERSON.

In preparation of this paper, Anderson studied 257 private cases, of which he has full histories, and which could be followed more closely and for a longer period than cases in hospital practice. These cases have been tabulated, noting the principal disease and also other morbid conditions from which the patients suffered at the time of consultation or during the course of their illness. Anderson concludes that it is characteristic of oral infections that, as a rule, they do not produce a single systemic lesion, but a group of allied conditions, not all being manifest at a time.

The author cautions against too hasty and sweeping generalizations. He urges that each suspected case be carefully and critically investigated, to determine if oral infection is responsible for or contributory to the symptoms. In his opinion, teeth should not be sacrificed on the advice of the physician. A competent and experienced dentist is best qualified to advise as to the applicability or limitations of dental treatment.

[*Indian Medical Gazette*, Calcutta, April 1918.]

Autogenous Oral Streptococcal Vaccines in the Treatment of Seventeen Cases of Sprue. BY LEONARD ROGERS.

The author here reports a series of seventeen cases as unselected and as consecutive as possible which have presented during the last four years. The particular strain of streptococci was not identified in the great majority of cases. Cultures were made when the tongue or mouth presented soreness or even small ulcers, but success was sometimes obtained during a quiescence of oral symptoms. The initial dosage was approximately 50 million, increasing to 200 million, at intervals at first of five days, ascending to ten days. In typical cases injections were continued three to six months.

The results of this vaccine treatment in cures and in marked improvement are strikingly superior to the results obtained by other methods. Rogers concludes that the data fur-

nished in this report go far toward supporting the view that sprue is essentially a streptococcal infection, originating in the mouth and spreading down the intestinal canal.

The case histories afford very interesting and suggestive reading.

Within the body of this paper is a brief mention of two cases of diarrhea associated with pyorrhea alveolaris successfully treated with oral autogenous vaccines.

[*Lancet*, London, June 8, 1918.]

Methods of General Anesthesia in Facial Surgery. BY R. WADE.

[*Journal of American Medical Association*, Chicago, July 20, 1918.]

Anesthesia and Antiseptics in Plastic Restoration of the Face and Mouth.

By A. E. ROCKEY.

Wade has found that there are two main difficulties in anesthesia for operations on the face and lower jaw: (1) Maintenance of good airway, and (2) the difficulty of avoiding interference with aseptic technique and field of view of the surgeon.

From the anesthetist's point of view, plastic operations may be divided into two main groups, those in which blood finds its way into the air-passages and those in which it does not. The following table gives a list of the various types of operations, together with the method of administration considered suitable for each case. Where there are alternatives the first is preferable.

Types of operations: Methods of anesthetization.

Lip plastics. C., C.E. + O₂; sitting up, intratracheal. Oil-ether per rectum, sitting up.

Cheek plastics. (A) Involving oral cavity: Intratracheal. C. or C.E. + O₂; sitting up. Oil-ether per rectum, sitting up.

(B) Not involving oral cavity: C. or C.E. by Shipway's warm-ether apparatus.

Chin plastics: Intratracheal; Kahn's tube.

Jaw operations: (A) Wiring fractures; also (B) Bone-grafting: Oil-ether per rectum; sterile anesthetic.

(C) Either of above cases with jaws splinted together. Sterile anesthetic.

Extensive burns of face: Oil-ether per rectum.

Anesthetizing the patient in the sitting-up

position in cases in which the blood is likely to find its way into the mouth during the operation has been found to be very satisfactory. Out of nearly 300 cases there have been no bad after-effects or complications.

In connection with this subject, Lovett (*Lancet*, June 22, 1918, p. 885) advocates preliminary tracheotomy and anesthesia through a tracheotomy tube. Lovett has used this method several times in the worst types of jaw cases with comminution of the mandible, laceration of the soft parts, and when the field of operation includes the oral cavity.

Mortimer (*Lancet*, July 13, 1918, p. 56) believes that for such purposes laryngotomy is usually preferable to tracheotomy, because by the former operation dangers of aspiration of blood from the wound and of opening up the deeper tissues are avoided. Wade (*Lancet*, July 13, 1918, p. 56) likewise prefers preliminary laryngotomy to tracheotomy, especially where there is much oral sepsis.

Rockey has been impressed with the difficulties signalized by Wade. The failure of surgeons to adopt the principle of an aseptic field in oral surgery is due to the inappropriate methods of anesthesia in general use. Rocky would remedy this condition. Ether inhalation by mouth through a large pharyngeal tube and a coffer-dam of gauze packing, when properly placed, is superior to any other method in a very large class of oral operations. It furnishes that efficient block between the operative field and the respiratory tract so necessary for the performance of ideal operations in this region, and makes possible a degree of asepsis in the operation not possible by any other method.

The apparatus devised and used by Rocky is shown in the paper by illustrations.

It is essential that the ether be given by someone competent to maintain safely such a degree of anesthesia as will prevent any attempt at vomiting, which might clog or displace the tube and break the asepsis of the operating field.

To secure that asepsis the following is essential: (1) Preliminary careful cleaning of the mouth by a dental surgeon. (2) After the introduction of the pharyngeal tube of the inhaler, and the careful placing of the gauze pack, the operative field is cleansed and sterilized as it is in any other part of the body.

[*Surgery, Gynecology and Obstetrics*, Chicago, August 1918.]

Aberrant Thyroid Tumor of the Tongue.

By MEYER A. RABINOWITZ.

This is an elaboration of a case report of this rare type of tongue tumor. The author estimates the total number of cases which have been observed to date to be about 70. These growths occur most frequently between the ages of fifteen and forty-five; 90 per cent. of all cases have occurred in females. The tissue of the growth is derived from persistent remnants of the anlagen of the thyroid gland.

These tumors are usually situated medially on the dorsum of the tongue, just below and behind the foramen cecum, varying in size up to that of a small apple, and almost invariably encapsulated. Clinically, local inconvenience is rare and constitutional symptoms are usually absent. The prognosis is favorable. Treatment is either thyroid feeding or surgical removal. The best operation is incision, with enucleation.

[*Anatomical Record*, Philadelphia, July 20, 1918.]

The Use of Sandpaper in the Preparation of Histologic Ground Sections of Hard Substances. By J. I. FANZ.

Fanz found that by the introduction of sandpaper in ground-section technique the time required to obtain thin, complete, workable sections was reduced to about one-quarter.

The object is clamped in an ordinary carpenter's wood clamp or small vise, and a section 1 to 3 mm. thick removed by saw-cutting with a jeweler's saw. This coarse section is cemented with dry-scale orange shellac to one end of a rather thick microscopic slide. Within five minutes the shellac is set so that grinding can be begun.

Grinding is accomplished entirely on sandpaper of different grades of coarseness, and the section is never dipped in water or oil. Flint, sand, emery, or carborundum papers are selected according to the hardness of the material to be ground. The flint paper used was of the following grades, Nos. 2, 1, 00, or 0000. Sheets were cut into pieces 3 x 5 inches and were held over a smooth hardwood block 3 x 4 inches while grinding. Brittle substances (e.g. enamel) grind best

on No. 00, using a light touch. As soon as a paper becomes clogged or worn out it is discarded for a fresh piece. Old sheets are used in grinding prior to polishing. As soon as the first surface is ground true it must be finished on No. 0000. Two pieces of this grade are rubbed face to face to remove large particles before grinding the section thereon. Polishing is done on the smooth side of a piece of sandpaper, the paper pulp constituting the buffing surface. Final polishing can be performed on a piece of smooth ground-glass, on the palm of the hand or on a razor strop.

After grinding and polishing one surface, the section must be removed (dissolving the shellac in alcohol) and re-cemented prior to grinding and polishing its second surface.

After this the technique of mounting is the same as for ground sections prepared by any other method.

[*Laryngoscope*, St. Louis, February 1918.]

Macroglossia Lymphangioma, with Report of Case. By R. D. SLEIGHT AND W. HAUGHEY.

The case was that of a girl, age six, of Polish birth. Family history was negative. The growth was first noticed at the age of six months, sequent to clipping the frenum linguae. The tongue, which usually is soft to the touch and nearly normal in size, with a spreading, superficial growth, is subject to marked enlargement by exacerbations occurring at irregular intervals. These are too infrequent as yet to justify operation.

The principal value of this report is the general discussion of the condition and the references to the literature of the subject, for which the case report serves only as a text.

[*Medical Record*, New York City, June 1, 1918.]

True Pruritus Ani: Its Association with Pyorrhea Alveolaris. By E. JAY CLEMONS.

True pruritus ani is the percolation of infection from within the rectal mucosa into the loose subcutaneous tissue of the anal canal. The organism which is the etiological factor in this condition is a streptococcus. The nature of the organism leads Clemons to believe that the rectal mucosa is not the primary site of infection. This view is fur-

ther confirmed to his satisfaction by the fact that in studying cases of true pruritus ani it is found that the patients are suffering from pyorrhea alveolaris.

Clemons failed to identify the streptococcal strain obtainable in the lesion. In other studies *S. fecalis* has been found. If this latter strain were proved to be the responsible agent, it would go far to exculpate the oral infection, because the streptococci of pyorrhetic pockets only rarely or never belong to the strain of *S. fecalis*.

[*Annals of Otology, Rhinology, and Laryngology*, St. Louis, December 1917.]

Dentigerous Cysts, with Report of Case. By IRA FRANK.

The case is that of a boy, age twelve and one-half, in whom there was first noticed at the age of six a swelling of the left maxilla just beneath the naso-labial fold. The growth was never painful; it increased slowly in size until at the time of presentation it equaled that of a small plum. The left second incisor, canine, and premolars had never erupted. The overlying mucosa was normal, and there was no glandular involvement. Palpation revealed a parchment-like crepitation. A radiograph distinctly showed a cyst with three of the missing teeth. Upon removal the cyst was found to be 3 x 3 x 2 cm. in size. Its outer wall was whitish and smooth, its inner surface pink. The wall was 3 mm. thick. Three rather small but well-formed teeth were found. The microscopic picture was typical, and showed evidence of acute and subacute inflammation.

[*Annals of Surgery*, Philadelphia, July 1918.]

Fibrin Paper as a Hemostatic Agent. By SAMUEL CLARK HARVEY.

Tissues and tissue products have proved themselves in recent years to be most efficient in stopping bleeding from multiple small vessels, from vessels in delicate tissue, and from sinuses. The peculiar advantage in the use of these tissues is that they, being absorbable, can be left within or upon the wound, thereby avoiding the danger of stripping off the coagulum.

In the present contribution, Harvey describes a method [for details, see original] for converting the fibrin of beef blood into a fabric easily kept, sterilized, and applied.

This fabric is found to correspond in effectiveness and amenability to absorption with the untreated fibrin, while being far more adaptable to the operating room technique. In dental practice this agent would lend

itself easily wherever a hemostatic was indicated, e.g. the moistened and softened "paper" could be packed under compress into a persistently bleeding tooth socket, and left there to be absorbed without further trouble.

PERISCOPE

Silver Nitrate in Root-canals.—We are being taught to deposit silver, from ammonia-treated silver nitrate, in root-canals by using formalin. Since experiments have probably shown that in electric ionization we drive our ions into and not through the root tissue, it occurred to me that this was the best way to deposit the silver in the root tissue, and experiments in practice seem to fully justify this treatment. Use a silver wire electrode.—F. D. PRICE, *Oral Health*.

To Measure the Circumference of a Tooth for a Gold Band.—Run a copper or aluminum wire through the rolls to make a very thin ribbon, or use the flat aluminum wire used in wireless work, but rolled thinner and annealed. It can be passed around the tooth and easily slips under the gum margin if desired, and may be pinched with the tweezers, as we make orthodontia bands. The correct measure of the circumference of a tooth or root can be obtained in this way quicker than the wire can be adjusted in the dentimeter.—F. D. PRICE, *Oral Health*.

Aid for Shoulder Crown Technique.—When adapting the gold base or fitting upon which the wax contour is to be developed, we frequently have trouble in making a good adaptation. This difficulty may be overcome by looping a gold wire around the upper axial third of the fitting. Twist it up tightly and then drive it down to the shoulder in a similar manner to the method employed for driving a hoop on a barrel. This wire loop will give a perfect and snug-fitting cap. If the wire is of 22-k. or 24-k. gold it may be left *in situ* while the crown is being developed, and finished in the usual manner.—F. W. FRAHM, *Pacific Dental Gazette*.

Sphagnum Moss as a Surgical Dressing.—Sphagnum moss is being extensively collected in England and her colonies for use as a surgical dressing. A number of eminent English surgeons and the army medical service have indorsed its use in the present emergency, and one eminent surgeon has declared that sphagnum dressing is superior to any cotton dressing, and that it has better absorbent qualities.

A number of the pharmacists, especially those in certain sections of Scotland, have aided in this service, and their botanical knowledge was highly useful in this connection.

It is stated that all that is necessary is to collect the moss, dry it in convenient clean places, and pack it in bags. Sphagnum moss grows so extensively in the marshes, bogs, and wet places throughout a very large portion of the United States that its value as a surgical dressing or packing and for other war purposes where cotton, oakum, or similar materials are now being used should be determined, and this problem is well worth the investigation of Red Cross and army medical authorities. If its usefulness for such purposes can be established, an endless supply is available at a normal cost.—EDIT., *Amer. Journ. of Pharmacy*.

Sterilization of Local Anesthetics.—A simple but effective method of preparing a sterile solution of cocain or other local anesthetic which may also contain epinephrin chlorid is described by Macnaughton-Jones. It consists in preparing a solution of sodium chlorid together with the anesthetic or anesthetics and epinephrin chlorid, each constituent being present in such quantity that a dilution with many (for instance, forty) times the volume of water will give a solu-

tion containing the requisite percentage of each. The preparation is placed in a sealed phial or ampule and kept until required. Sterile water is added immediately before injection. Experiments demonstrate that even if the preparation be inoculated with the ordinary forms of bacterial contamination, the presence of concentrated salt renders it sterile in a few days. A simple method of preparing the concentrated solution is to take the quantities of anesthetic, salt, etc., required per 1000 and dissolve in water, but make up to 25 instead of to 1000. The concentrated solution which Macnaughton-Jones prepared contains procain 3.25 (13 per cent.), sodium chlorid 3.25 (13 per cent.), epinephrin chlorid solution (1 in 1000) 8.0 (32 per cent.), water by weight (or metric), add 25.0 (100). If a 2 in 1000 (0.2 per cent.) solution of cocain be desired, the formula would be modified as follows: The osmotic pressure of such a solution is only equal to that of a 0.35-1000 sodium chlorid. and consequently about 3.65-1000 of this salt is added, but inasmuch as cocain produces anemia the epinephrin may be reduced if desired. The concentrated solution: Cocain hydrochlorid 2.0 (8 per cent.), sodium chlorid (approximately) 3.75 (15 per cent.), epinephrin chlorid (1 in 1000) 6.0 (24 per cent.), water by weight to 25.0 (100).—*Journ. Amer. Med. Association.*

Gold Foil Fillings.—What do we seek to accomplish in the operation of filling a tooth? Is not the primary object to stop the progress of decay toward the dental pulp, and save its life? To preserve it in its health? To immunize the tooth surfaces? To restore the tooth to its original form and function, and to protect the investing tissues? If this then is our duty, I ask what material has time proved to be first in accomplishing these results? With the rubber dam in place, the cavity is prepared under dry conditions, with less pain, and we know we secure a superior cavity. We know when we fill that cavity with gold foil, fresh from the flame, we are using a sterile material, and we have had demonstrated for forty years the immunity of those fillings by men who have gone before us. When properly performed, these operations have stood the test of time, first in order of all the filling materials. I plead with you, do not let the meteor going through the heavens hide from view the stars of the first magnitude. Do not let the inlay draw your attention away from the technique of gold foil, because in the average number of cases I believe we know and can prove that gold foil can be not only better adapted to

those cavity walls, but quicker. It is foolishness to discuss which is the quicker. That is not what we are after. Which is the better? What is the material with which we may use to our great advantage the elasticity of the dentin, and place in the cavity a filling which the dentin will grip continuously and hold there secure against moisture and bacterial invasion? Only one material—gold foil. Somebody said it was "so difficult to use." I challenge that statement. It is difficult because we have not studied it; it is difficult because we do not comprehend the facts entering into the operation. Five or six things are necessary, we are told, in securing a good inlay—temperature, change in volume of materials used, etc. The operator in gold foil may secure absolute adaptation of the material to sterile cavity walls and eliminate all chances, in one operation. Where gold foil is indicated let us use it honestly, carefully, and scientifically. It will then demonstrate its wonderful possibilities.—J. M. PRIME, *Journ. N. D. A.*

Synthetic Technique.—Prepare the cavity as for a gold filling, with square margins and no bevels whatever. Chill the slab to a temperature of about 65° to 70° F. and wipe the slab and spatula with grain alcohol. Have ready instruments of tantalum, ivory or agate—always an agate spatula—celluloid matrix strip, pliers, and cocoa butter. Next dry out the cavity with alcohol, and wherever feasible, especially when deep, line the cavity with Caulk's cavity lining; then adjust the celluloid matrix.

Place the powder and liquid on the slab, taking out about twice the amount of powder as of liquid. Mix promptly on exposure on the slab, that is, complete the mixing within a minute and a half. This is easily accomplished if a large quantity of powder is introduced into the liquid and spatulated only enough to saturate it, followed with successive small quantities until the mass is just past the point where it is wet, but is still plastic.

With the celluloid matrix strip in position, introduce the synthetic cement into the cavity, working it well into the undercuts and against the cavity walls. Fill the cavity with slight excess, bring the celluloid matrix strip around the filling and hold it stationary for 3½ minutes by the watch, with a firm pressure but without burnishing. At the expiration of 3½ minutes the strip will release itself. Immediately coat the filling with cocoa butter to exclude the air, and allow it to stand undisturbed for ten or fifteen minutes, accord-

ing to the size of the filling; then dress down with abrasives carrying cocoa butter.

In approximal cavities it is permissible to use bud-shaped, fine grit, clean carborundum points carrying cocoa butter on the lingual surfaces, where they are inaccessible to disks and strips. Follow with fine-grit sandpaper disks and strips, and finish with finest cuttlefish disks and strips, always carrying cocoa butter. It will be found that a better color and finish will be obtained if the final finishing is deferred until a subsequent sitting. Before removing the dam, wipe off the cocoa butter with dry cotton, and immediately coat the filling with varnish. Do not use a varnish containing alcohol; as it will dehydrate and change the color of the filling.—GEO. D. SMITH, *American Dentist*.

Chlorin Antiseptics.—The antiseptics of the chlorin group which are most commonly employed in the treatment of infected wounds are the following: (1) Hypochlorous acid and its sodium and other salts, including Dakin's solution. (2) Chlorazene (chloramin-T), the abbreviated name for sodium-toluene-sulfon-chloramid, which is employed in an aqueous solution. (3) Dichloramin-T, the abbreviated name for toluene-sulfon-dichloramin, which is used only in an oily solution.

In most respects, the action of the various chlorin compounds is essentially similar, though each possesses certain properties which render it more or less suitable for particular purposes. As a matter of convenience, it may be desirable to give a short *résumé* of these considerations, the results of which are mostly taken from the experiences of Dakin, Carrel, Dunham, Lee, and others, as well as our experiences at the West Side Hospital.

(1) Hypochlorous acid and hypochlorites are best suited to cleansing septic wounds by irrigation. They markedly assist in the dissolution of necrosed tissue: they are unstable and very reactive, and must be renewed frequently in all parts of the wound, this being best accomplished by an intermittent method of instillation. But the complexity of the apparatus necessary to obtain the ideal result, that is, by frequently renewing the antiseptic, makes this method quite cumbersome.

(2) Chlorazene (chloramin-T), used in aqueous solution, is more stable, exerts more prolonged antiseptic action, and is considerably more effective than the hypochlorite when acting in the presence of blood. For details concerning the preparation of solutions of the hypochlorites and chlorazene, we refer to the publications of Dakin and Carrel.

(3) Dichloramin-T dissolved in a special oily solvent may be sprayed upon wound surfaces or poured into accessible parts of deep wounds. It yields moderate amounts of the antiseptic to watery media such as the secretion from wounds or mucous membranes, but yields much greater amounts when used on dry surfaces. It is suitable for cases requiring prolonged antiseptic treatment and for first dressings of recent wounds which do not require irrigation. It is also used for nasal and oral and for ocular antiseptics.

By reason of its availability in oily solution, dichloramin-T has a great advantage over the other chlorin antiseptics in that it may be used in high concentration, and its action is of much longer duration. The application of the oil is extremely simple, and it ordinarily need not be renewed more than once in twenty-four hours.—L. I. MILLER. *Amer. Journ. of Clin. Medicine*.

OBITUARY

Dr. George A. Maxfield.

[SEE FRONTISPIECE.]

DIED, Tuesday, July 30, 1918, in his seventieth year, at his home in Holyoke, Mass., after an illness of several weeks, GEORGE ARTHUR MAXFIELD, D.D.S.

Dr. Maxfield was born at Chicopee Falls, Mass., October 29, 1848, the son of Arthur

L. and Orrissa (Anderson) Maxfield. Dr. Maxfield's father was a prominent cotton goods manufacturer of New England, and removed from Merrimac, Mass., to Holyoke in the year 1854.

Dr. Maxfield received his early education in the public schools of Holyoke, and in 1879 entered the University of Pennsylvania, de-

partment of dentistry, from which institution he received the D.D.S. degree in 1881. Immediately after his graduation Dr. Maxfield opened an office in Chester, Pa., where he practiced dentistry for two years. In 1883 he returned to Holyoke, where he established himself in the practice of his profession, remaining there until the time of his death.

Dr. Maxfield was conspicuously successful in practice, especially as a consulting dentist in the diagnosis and treatment of unusual and obscure oral diseases. Dr. Maxfield was for years a leading citizen of Holyoke, always interested in every movement which concerned the betterment and uplift of the community. He was an active member of the Second Baptist Church of Holyoke, which he served as clerk for many years.

Dr. Maxfield was long and favorably known as one of the most active and enthusiastic dentists of his district. He was closely associated with every development of the dental profession in the Connecticut Valley, and was particularly active and influential in the Massachusetts State Dental Society. His conscientious endeavor was always for the elevation of the standard of dentistry by his influence and efforts in the various dental societies with which he was connected. He was particularly interested in the younger men of the profession, and was always willing and anxious to lend them a helping hand. He was for eleven years secretary of the Connecticut Valley Dental Society, in which society he continued his activity when it was merged with the New England Dental Society, and later into the present Northeastern Dental Association. He was president of the Massachusetts Dental Society in 1895, and as vice-president of the society the previous year he was one of three members who planned the reorganization of the state society into seven districts, and helped to draft the constitution and by-laws for the reorganized society.

He was appointed a member of the Board of Registration in Dentistry in 1897 by Governor Roger Walcott, and served on that board for fourteen years, retiring in May 1913.

Dr. Maxfield was typical of New England manhood. He was a staunch supporter of the dental law, and, together with those associated with him, was responsible for the high standard which dentistry has attained in New England, and particularly in Massachusetts.

He was a frequent contributor to the dental literature, and also the inventor of several useful dental appliances. He was the joint inventor with Dr. Newton Morgan of the well-known Morgan-Maxfield disk mandrel, which has for many years been one of the standard dental appliances used by dentists throughout the country.

In addition to the societies already mentioned he was a member of the National Dental Association, and honorary member of the New Hampshire, Vermont, and Connecticut State Dental Societies.

Dr. Maxfield was married in 1871 to Miss Elizabeth R. Bennett of Holyoke, who died in 1882. In 1885 he married Miss Martha H. Currier of Holyoke, who survives him. His remains were interred in the city cemetery of Holyoke, Friday, August 2d.

Dr. Lloyd Allen Osborn.

DIED, Tuesday, July 24, 1918, at Fremont, Iowa, from drowning, LLOYD ALLEN OSBORN, D.D.S.

Dr. Osborn was born August 13, 1890, at Stuart, Iowa, the son of William T. and Mary Osborn. Dr. Osborn obtained his early education in the high school at Valley Junction, Iowa, and later attended Drake University at Des Moines, Iowa. He entered the State University of Iowa dental department in 1912, and was graduated from that institution in 1915. He immediately opened an office in Fremont, Iowa, where he practiced his profession until the time of his sad death.

Dr. Osborn held a commission as 1st lieutenant in the Dental Reserve Corps of the United States army, and was expecting a call into the service when death overtook him. He was active in religious work, and was a regular attendant of the Presbyterian Church in Fremont. At one time he was a teacher of a class of boys in Sunday-school, and later became interested in the boy-scout movement. He became a scoutmaster, and organized a troop at Fremont. He was on a scouting expedition with his troop on the river near Fremont, and was attempting to save one of the boys of his troop who had accidentally fallen into the swiftly moving current of the river when he lost his life, sacrificing it in

an unselfish and heroic endeavor to rescue one of his youthful companions.

Dr. Osborn was a member of the Iowa Dental Society. He was married May 29, 1918, to

Miss Eva Allen of Sioux City, Iowa, who, with his mother, father, and sister, survives him. His remains were interred at Valley Junction, Iowa, July 23d.

DENTAL COLLEGE COMMENCEMENTS

University of Iowa, College of Dentistry.

At the annual commencement exercises of the College of Dentistry of the State University of Iowa, held June 12, 1918, in Iowa City, Iowa, the degree of Doctor of Dental Surgery was conferred on the following graduates:

ARMY AND NAVY DENTAL NEWS

Twelve Months with British Prisoners of War.

By W. J. LAW, L.D.S.Eng.

WHEN Mr. Woods decided to go out to Switzerland for two months to undertake the dental treatment of our prisoners of war interned there, the North Midland Branch decided that the work thus begun should, if possible, be continued, and for this purpose opened a subscription list, which was liberally responded to. Mr. Woods' two months lengthened to six, and the good work he did created a demand for a similar service at the other main center of Switzerland. So plans were altered, and after the usual War Office delay, permission was given to send out another dentist to Chateau d'Oex. The scheme met with the enthusiastic and wholehearted support of Sir Arthur Stanley and the Council of the British Red Cross, who made a very liberal donation to the funds, while at the same time giving the branch committee complete liberty of action.

Early in April 1917, then, I was asked to undertake the work, and came up to London on a begging expedition. Never had beggar an easier task! On all hands the dental firms gave and lent and reduced prices with the greatest generosity and readiness. Messrs. de Trey alone offered all they could to completely equip the work, free of cost, and are constantly begging among their American friends for more! Messrs. Ash lent a chair and electric engine free of cost. Messrs. Parke-Davis, "Kolynos," Courtin, and others were equally generous, and only in one case was any refusal made.

The end of the month found my wife and me on the deck of the steamer, Red Cross armlets on our sleeves, some three to four hundredweight of luggage in the hold, on our way to Switzerland. The tedious journey of three days was greatly ameliorated by the Red Cross arrangements. At all places they gave constant help, provided hotel accommodation in Paris, dealt with baggage, booked seats on the trains, and did everything possible to minimize discomfort.

AT LEYSIN.

Arrived in Switzerland, we were first of all sent to the tuberculosis center and sanatorium of Leysin, situated 4000 feet above sea level, overlooking the Rhône valley; with the Dent du Midi opposite, it was indeed an ideal spot, "where every prospect pleased, but," alas! "only man was vile!" For its whole population is a victim to one form or other of the dread bacillus. Balconied sanatoriums rise one above another almost to the sky line! Here the famous sun-cure establishments of Dr. Rollier for joints, spines, etc.; and there the other establishments for lungs! Every inhabitant, from the shopkeeper to the chambermaid, was ill, and every nationality seemed to be represented in the village. French, Swiss, Greeks, Italians, Serbs, Roumanians, Poles, Russians, Belgians, and even Siamese, were all in our hotel; while, of the prisoners, we had Belgians, French with their Colonials, Arabs in gorgeous red and blue uniforms, with marvelous gold embroidery, turbans, and fezzes. Our own British Tommies, Colonials, and Indians, in their khaki, relieved only by Scotch bonnets, formed a sober background. Among our twenty-seven Indians, who lived in a separate chalet, killed and cooked their own food, fourteen different tribes were represented, and weird and wonderful were the quarrels that ensued in as many different dialects. A rather depressing prospect at first, tempered in the end by the knowledge that in the wonderful restorative properties of the Alpine air and sunshine, men, broken in prison camps of Germany, had more than an even chance of restoration to health and usefulness.

Swiss railways and habits do not, to say the least, hustle; but at last all was ready. An ideal surgery in the main hotel was put at our disposal, with a polished oilcloth floor. A light and wide balcony, overlooking the valley, equipped with pump chair, electric engine, fountain spittoon, and an abundance of hot and cold water, made admirable working conditions. Treatment was entirely free and voluntary, and soon patients swarmed in. In a very short time dentistry became the

fashion, and the amount done to each patient a subject for eager discussion among them. Ribald parodies appeared at the "Hut" concerts, and a lecture on "Teeth, and How to Take Care of Them" sent up the price of apples at the next-door greengrocer's.

The men themselves were an epitome of the war. As they told their stories, half-forgotten incidents of, it seemed, ages ago came back to living memory. Here were Lancashire Fusiliers taken on the first day at Mons; Connaught Rangers "left behind" on the famous retreat: men of the Marne and Aisne. My own orderly, a Royal Scottish Fusilier of twenty-one years' service, came straight from India, and, as part of the immortal 7th Division, was captured at the first battle of Ypres; men of the new army picked up after Loos; Canadians from the second battle of Ypres; Irishmen flattered and favored until they refused to betray their salt when cajoled by the visionary and traitor Casement at Limburg, then starved and buffeted in all kinds of fiendish methods for their loyalty; men who had lived through the horrors of Wittenburg and many another equally vile but less well-known camp, all cheery, all difficult to convince that rest, fresh air, and sunshine had anything at all to do with their cure, but with the conviction that the worst crime in the calendar was to be dirty or slovenly in person or dress, and that the next was to work for the Germans, and that the main duty of life was to annoy and impede their captors in every way possible.

Dentally, of course, the large majority were in a bad way. We, who know the almost entire lack of dental attention which was characteristic of our old army system, will not be surprised at this. Treatment in the large majority of cases had to be radical. Nitrous oxid is almost, if not quite, unknown in Switzerland; so local anesthetics had to be resorted to in every case that it was safe or possible to do so. Conservative work consisted chiefly of plastic fillings and porcelain crowns. No coal-gas is to be had in these mountain resorts, so soldering was almost impossible, and pivot or gold-shell crowns rather difficult to do. Some few, in cases where nothing else was possible, were set up and sent to a laboratory at Zurich to be finished. A similar procedure made the finishing of dentures possible.

Pyorrhea was conspicuous by its rarity. Teeth were dirty, a large number of men had gingival tartar in the upper as well as the lower jaw, but, contrary to civilian experience—which is that pyorrhea is almost always an accompaniment of tuberculosis—few real pockets were found.

AT CHATEAU D'OEX.

Extractions and fillings finished, together with some dentures, we moved on to the much larger camp of Chateau d'Oex. Here were some 750 men and officers disabled and ill in various ways. Accommodation was difficult to obtain, the hotels being full, and only built for holiday purposes. But at last we found two rooms on the ground floor of a large old chalet which had been used by a dentist formerly, and so had water and a basin already fitted. Here, with a little furniture and floor covering, we soon were once more installed, and work, as before, began to pour in. Hardly had we begun, when the long and eagerly talked-of repatriation became a reality. The Commission actually arrived, and men passed for home began to wear the real Blighty smile—the sort that do what you will won't come off, and is worn sleeping or waking, at work or at play. Much running to and fro ensued: all the dentures at Leysin had to be finished, some of them at and up to the last minute. The great day arrived—one denture had to be adjusted in the train—even as a parting benediction one tooth was extracted in that same train, and amid scenes of great excitement 250 left for Old England once more, cheered by large crowds all the way along the line, even at Geneva, at 3 o'clock in the morning. Once more work settled down again into its usual routine, and our thought turned to the new arrivals. When would they come, and what would be their condition when they did arrive?

Late in November the first party turned up. Much to our relief they seemed in much better physical and mental condition than the first parties, though the dark blue, almost black, uniforms supplied by the home authorities, to which the Germans had thoughtfully added stripes and patches of yellow cotton, to render escape more difficult—in some cases even cutting the cloth away and inserting the patch bodily in the suit—made anything but a pleasing picture. However, suits of khaki soon altered this, and the sun gave a tan and color to pasty faces, which at once improved 50 per cent. of the men, in appearance at any rate. Another batch arrived late in December—too late for Christmas Day, alas!—and their condition was much worse than that of their predecessors, though the same remarks apply. One interesting thing was that they had been in Mannheim on Christmas Day, and had seen and cheered like mad the British aeroplanes which gave that city a very unwelcome Christmas present. Among them, too, were our first

civilian prisoners of war: we had had several naval men, and now we had men of our not less gallant mercantile marine. More than one of these were veterans of over seventy—there seems to be, apparently, no age limit on the sea—and of their cheerfulness, optimism, and patriotism, no praise can be too warm. A piece of work which I think gave me more satisfaction than any other that I have done out here was to replace a full upper and lower set for one of these men; his own had been lost during his three hours' immersion in the sea after the torpedoing of his vessel, and he had steadily refused to have them replaced in Germany because it was helping the enemy. Since the great first repatriation others have followed at intervals of, roughly, three months, and the places vacant are being filled up with fresh men from Germany; so a constant stream of new faces and fresh work runs past us.

EFFECTS OF THE INJURIES UPON THE MEN.

What of the men themselves? Slowly and reluctantly one has come to the conclusion that none, or hardly any, can be called normal. Whether they will ever be so again is to be doubted. Behind them lies a land of ghastly horror. The door has been shut, it is true, but the memory remains an ever-present nightmare. Rarely, and only with the most reluctance will they speak of it. They want to forget, but they cannot. Any and every recital of actual, and even supposed, horrors cannot reproduce the actual atmosphere of dumb and intolerable suffering, from which, as by a miracle, they have come out alive; and the impression of it on their lives is indelible. They are scorched and branded as with a red-hot iron. Wounds may heal, physical disabilities they get used to, but the mental disability remains. And yet they make one proud of one's native land. With all their temptations real crime is rare. Such disturbance as occurs is mainly due to an excess of the native spirits, raw and fiery. Immorality, so far as we can tell, is almost *nil*. The Swiss are a moral people, but every Swiss girl loves the British soldier, and so the fact is the more remarkable. I have already mentioned their cleanliness, and one can add to this their pride in, and care of, the rooms they inhabit. Almost every bedroom is decorated with cards and photographs: few are they from which flowers are absent in spring and summer, and the managers of the best and most expensive hotels in the region are glad to have the British as their guests. The worst thing was lack of occupation. Lately something has been

done to remedy this. Classes in woodwork, metalwork, motor driving, repair leatherwork, etc., have been opened, and here a large farm has been taken and planted with potatoes and vegetables; toys designed and made by the men themselves have had a ready sale, and basket-making and fancy needlework have been taught to the men in hospital, but it is difficult to find suitable work for all.

ATTITUDE OF THE SWISS.

Lastly, what about the Swiss attitude to us all? It must be borne in mind that Switzerland is a federation of many cantons, some French, some German, and some Italian-speaking. While the French-speaking are very pro-Entente, as a rule, it by no means follows that the German side is wholly sympathetic to Germany—far from it. In the second place, when the first arrangements were made, food was plentiful, whereas now it is getting very scarce, owing to the increasing shortage of shipping. Our bread ration is the smallest in Europe, save Holland, I believe, and living costs more than twice what it does in England. But, even with these drawbacks, my own personal experience has been nothing but favorable. The mere fact that I am allowed to do the work, though I have no Swiss qualification, is proof of that. Doctors and officials make things easy, and an appointment with the dentist overrides any other. Our Swiss *confrères*, far from looking upon us as interlopers, have constantly offered to do anything in their power to help our work.—*British Dental Journal*.

Federal Vocational Education.

THE federal board of vocational education is proceeding vigorously with its work in connection with the re-education of disabled men of the military services and their return to civil employment. This task was unanimously delegated to the board by Congress in the "Smith-Sears act" of April 6, 1918. This means much to these men who have suffered impairment of their earning capacities. The re-education and subsequent placement in civil life will in nowise affect the compensation the men will receive on account of disabilities from the war-risk insurance bureau. Co-ordination with other departments of the Government will be necessary to secure a smooth working plan. The three duties laid upon the board by law relative to the disabled men are: (1) Advisement, to ascertain what the man may want to train for, and to guide him into that vocation best suited to his capabilities, and which offers most substantial

expectations of steady and remunerative employment: (2) Training, by which, after his aim is fixed and decided, he is made efficient in that trade or profession; and (3) Placement, which graduates him out of the student and into the wage-earning or self-sustaining class, the latter made possible by the re-education he has received. The advisement will begin in the hospital in closest harmony with the military authorities, and at the earliest possible moment, so that any exercise or occupations given the patients for their therapeutic or curative value may, when possible, be a process in the scheme of re-education, and have a double and practical purpose aside from their well-recognized place as restorative media. The federal board must either establish its own schools for the work of rehabilitation or make arrangements with public and private schools throughout the country to carry on approved courses of instruction for these disabled men, the entire cost to be borne by the national Government. —*Army and Navy Register*.

The New Zealand Army Dental Service.

THE High Commissioner of New Zealand has issued an article, compiled by Mr. Malcolm Ross, describing the work of the Dental Corps of the New Zealand Army. Mr. Ross says:

It was in August 1915 that the New Zealanders started, at Cape Helles, the first dental hospital known in British warfare. It was established in a marquee on the cliffs above the Lancashire Landing by an officer who is still with us in France. There were two operators and six mechanics, the latter drawn from men in the famous 29th Division, several of them with degrees, but who were drawing only one shilling a day. Generals and other officers coming down from the front used to look in and express their astonishment at the establishment of a dental hospital in the war zone.

At the present moment the New Zealand dentists are working harder than ever, and saving to the army many a man who would otherwise become at least temporarily unfit for active service. Preliminary work was done in New Zealand before the force sailed, more was done on the troopships during the long voyage; still more in Egypt, while the work accomplished in the early days on Gallipoli undoubtedly kept hundreds of men in the firing line a time when men were sorely needed.

It has already been published in England that the teeth of the Mediterranean Expedi-

tionary Force that landed at the same time as we did on the peninsula were often in an unsatisfactory condition. Indeed, the position was considered so serious that the British Surgeon-general approached the G.O.C. of the New Zealand Force for a loan of several of its dental officers, which loan was readily granted. The Australians also were without dentists, and in their case, again, New Zealand supplied the want.

Since then there has been a general advance in army dentistry, and the English, as well as the Australians and the Canadians, have well-equipped dental corps, but New Zealand still leads, inasmuch as it is the only country along the entire Allied front that has a dental hospital in the field, or, in other words, in the divisional area. The Germans, with their usual thoroughness, have their dental surgeons close up, and, as the result of always having recognized the necessity for an efficient dental service, the condition of the teeth of their troops leaves little to be desired.

The general practice adopted by us is a system of conservative dentistry, with the object of keeping the troops medically fit during the period of the war, the work being expeditiously performed, so that both officers and men may be returned to their units without delay. So far as New Zealand is concerned, there is what may be termed a complete dental chain. To begin with, there is provision for dental treatment in the training camps in the Dominion. On arrival in the United Kingdom they are again examined by the dental corps at the reserve group, and if necessary they receive further treatment until they can be certified fit to proceed to France. At the base depot in France there is another dental section, while with the division in the field there is a fully equipped dental hospital. Beyond this, in the forward areas, there is further provision for dental treatment.

But the system does not end here, for by a wise provision the soldiers who are no longer fit for service have their mouths made normal by the dental corps before they are discharged in New Zealand. This, as has been pointed out by the director, will have a very valuable effect on the nation in the next decade, since it gives the opportunity to the profession of combating dental caries among a class hitherto almost unapproachable.

From September 1914 to the end of January of the present year the number of extractions reached the large total of 57,257, the number of fillings 73,066, root-fillings 8324, minor operations 23,614, dentures 21,565, repairs 15,212. The number of patients treated reached a total of 114,677.—*British Dental Journal*.

Slackers Wanting Teeth Pulled!

ACCORDING to the Provost Marshal-general the department of Justice has turned over to that office information which it has received tending to show that registrants in certain localities desiring to avoid military service have sought to have teeth extracted so as to render them subject to physical disqualification. A dentist in New York State advises that several would-be slackers have approached him with requests to have teeth extracted for this purpose. The Provost Marshal-general desires to warn all dentists against permitting themselves to be a party to practices of this sort, and to call attention to the fact that severe penalties are provided in the law for any person conspiring to aid another to avoid the draft.—*Army and Navy Register*.

Sixty-eight Vacancies in the Dental Corps, U. S. Army.

(1) The Acting Surgeon-general of the army announces that there are, at the present time, 68 vacancies in the dental corps, U. S. army, and that examinations for the appointment of dental surgeons will be held at various points in the United States, on Monday, November 4, 1918.

(2) Application blanks and full information concerning these examinations can be procured by addressing "Surgeon-general, U. S. Army, Washington, D. C."

(3) The dental corps is a constituent part of the Medical corps, and consists of officers in the grades of colonels, lieutenant-colonels, majors, captains, and first lieutenants. Appointments are made at the rate of 1 for each 1000 [now approximately 1 for each 500—Ed.] of the total strength of the regular army authorized from time to time. The law requires that first lieutenants of the dental corps shall serve five years in that grade before being promoted, but for the period of the existing emergency this provision has been suspended by act of Congress, and after one year's service as first lieutenant, a dental surgeon is eligible for promotion to the grade of captain, after which promotions are made in order of seniority as vacancies occur in the higher grades.

(4) No applicant may under existing law be commissioned in the dental corps unless he is between twenty-one and thirty-two years of age, a citizen of the United States, a graduate of a standard dental college, and of good moral character, nor unless he shall pass the usual physical examination required for appointment in the medical corps, and a professional examination which shall include tests of skill in practical dentistry and of

proficiency in the usual subjects of a standard dental college course. Whether or not the applicant is married has no effect upon his eligibility for the dental corps.

(5) Application for appointment must be made in writing to the Surgeon-general of the army, upon the prescribed blank form. All the interrogatories on the blank must be fully answered. In compliance with the instructions thereon, the application must be accompanied by testimonials, based upon personal acquaintance, from at least two reputable persons, as to the applicant's citizenship, character, and habits. The selection of the candidates is made by the Surgeon-general from the applications submitted, and a formal invitation to report for examination to the most convenient examining board in each case will be issued by him.

(6) The examinations are conducted under instructions from the Surgeon-general, and usually last six days. No allowances can be made for the expenses of applicants undergoing examination, whether incurred in travel to and from or during their stay at the place of examination, as public funds are not available for the payment of such expenses. Each applicant, upon presenting himself to the board, will, prior to his physical examination, be required to submit his diploma as a graduate of a standard dental college. Should he fail to do so the examination will not proceed.

(7) A first lieutenant receives \$2000 per annum; a captain \$2400 per annum; a major \$3000 per annum. These salaries are increased by 10 per cent. for each period of five years until the maximum of 40 per cent. is reached, excepting that the maximum salary of a major is \$4000 a year, and that of a lieutenant-colonel and colonel is \$375 and \$416.66 per month, respectively. In addition to their pay proper, they are furnished with a liberal allowance of quarters according to rank, either in kind, or where no suitable Government building is available, by commutation. Fuel and light therefor are also provided. When traveling on duty an officer receives mileage for the distance traveled. On change of station he is entitled to transportation of professional books and papers and a reasonable amount of baggage at Government expense. Groceries and other articles for their own use may be purchased from the quartermaster at about wholesale cost prices. Dental surgeons are entitled to medical attendance and hospital treatment without charge other than for subsistence.

(8) Officers of the dental corps are entitled to the privilege of retirement after forty years' service, or at any time for disability incurred in the line of duty. On attaining

the age of sixty-four, they are placed on the retired list by operation of law. Retired officers receive three-fourths of the pay of their rank (salary and increase) at the time of retirement.

(9) In order to perfect all necessary arrangements for the examination, applications must be in the possession of the Surgeon-general at least two weeks before the date of examination. Early attention is therefore enjoined upon the intending applicants.

Promotions.

Army Dental Corps.

THE following appointments (promotions) are announced (August 31st):

To be MAJORS: Cpts. Merton M. Postle, James L. Clements, and John P. Garriott.

To be CAPTAINS: 1st Lieuts. Benjamin Naidis, Reginald L. Felton, and Edgar T. Haynes.

Announced September 7th:

To be CAPTAINS: 1st Lieuts. Wall M. Billings, Wm. I. Setzekorn, John F. Ailworth, Gerald F. Stoodly, Bernard Ragland, Walter F. P. Zell, Edwin V. Morris, Herman J. Keyser, Daniel Jutton, and Thomas W. Conly.

Announced September 14th:

To be CAPTAINS: 1st Lieuts. Jackson H. Smith and Blake A. Sears.

Teaching Oral Hygiene to French Children.

AMERICAN RED CROSS.

American Red Cross worker showing French children the importance of taking care of their teeth and how to keep them clean. Over 173,000 people attended this "child welfare" exhibition. The motto CLEAN TEETH DO NOT DECAY is as applicable in our own "second line of defense" as just behind the front.

Preparedness League of American Dentists.

ORGANIZED UNDER THE AUSPICES OF THE N. D. A.

THE DENTAL COMMITTEE OF THE GENERAL MEDICAL BOARD, WHICH IS THE AGENCY FOR THE MEDICAL AND DENTAL PREPAREDNESS IN THIS WAR EMERGENCY, HAS MADE IT POSSIBLE FOR EVERY DENTIST IN THE UNITED STATES TO ASSIST IN THE WORK, UNDER THE SUPERVISION OF THE PREPAREDNESS LEAGUE OF AMERICAN DENTISTS.
HEADQUARTERS AT 50 EAST 42D ST., NEW YORK, N. Y.

FROM THE PRESIDENT.

We are starting on our third year with the following officers elected at our annual meeting in Chicago on Aug. 9, 1918:

President—J. W. Beach, Buffalo, N. Y.

Vice-president—J. D. Millikin, San Francisco, Cal.

Secretary—O. A. Oliver, Nashville, Tenn.

Treasurer—L. M. Waugh, New York, N. Y.

Representing the Surgeon-general's Office—Lieutenant J. V. Gentilly, New York, N. Y.

Director-general—W. D. Tracy, New York, N. Y.

We deeply regret the resignation of Dr. C. F. Ash as Director-general, but activities in other directions made it imperative. He has been appointed a member of a committee for the conservation of platinum, an office which will occupy a large share of his time. His services as Director-general have been of inestimable value to his country and to the League, and a more efficient incumbent could not have been found. I know every member joins me in these sentiments, together with good wishes and the hope of long service to his Government.

The assurance given by Dr. Ash that his interests are with the League at all times, also that his services will be given just as freely as before, somewhat mitigates our regret at his resignation; nevertheless, his active management will be greatly missed.

THE NEW DIRECTOR-GENERAL.

Dr. Tracy, our new Director-general, has been director for the department of the Northeast as well as chairman of the New York unit of the League. He is, therefore, especially qualified to assume the broader duties, he having been, as it were, the understudy of Dr. Ash. No better selection could have been made, and it gives me great pleasure and satisfaction to indorse him in every particular.

This step means for him great sacrifice, but he has offered himself willingly and gladly to this service. Every worker of the League will receive the fullest co-operation from his department, and I know that he will receive an equal return from our members and that the benefits of our work will continue to increase.

COLONEL LOGAN AND THE LEAGUE.

In his President's address before a great audience of more than 5000 people in the Auditorium Theatre, Chicago, on the evening of August 6 last, Colonel Logan, as President of the National Dental Association, spoke in most appreciative terms of the service the League has rendered in making the registrant dentally fit for military duties. We are deeply grateful for such expression, yet feel that our members are justly entitled to it. No one will ever know the amount of free service given by the dentists of America, not more than one-third of which will ever be recorded.

A suggestion was made by Colonel Logan that, inasmuch as the military camps are now well equipped, the army dental department is in a position to do the necessary fillings for the recruit after entering the service; therefore, it is his desire that the League give special attention to reclaiming the dentally unfit in order to place them in class A. By so doing, the dentist may render the greatest service to the Government by augmenting our fighting forces.

Continue doing all necessary fillings and extractions as heretofore, for there is more dental work needed by our soldiers than could be done if every one of the 50,000 dentists of the United States should devote his whole time to this purpose. Shoulder the additional burden manfully and cheerfully for the sake of our own boys who are laying down their lives by the thousands that we may spend our declining years in our own peaceful coun-

try and under the protection of the flag that shall bring enduring democracy to the whole world.

Assure Colonel Logan of our co-operation in this way.

THE WHEELS OF THE LEAGUE.

The Dental Motor Car Exhibit in Grant Park, opposite the Auditorium Hotel, during the meeting of the N. D. A. at Chicago, proved one of the most interesting features of the convention. Chairman Weaver secured a host of friends for the car, and its future usefulness is assured. The Red Cross soon will begin shipping them overseas for active service at the front.

It remained, however, for Dr. Ottolengui to again demonstrate his resourcefulness and originality of thought by inaugurating a plan for securing a Dodge motor car for the special use of the dental officers in each military camp. This movement is much needed, as a motor car will greatly increase the usefulness of the officers by transporting them rapidly on their daily round of duties.

Through his activity, ably assisted by Dr. F. M. Casto, more than \$1100 was raised in less than one hour at the meeting of the American Society of Orthodontists, and he immediately ordered a car delivered at Camp Greenleaf. Another one has been ordered for Camp Upton, and more will follow as rapidly as possible. These cars will be presented through the League, and will pass from commandant to commandant as changes occur in the camps.

OUR STUDY COURSE.

One of the most urgent duties of the League is to make available a course in war oral and dental surgery for the civilian practitioner. We are exerting every effort to have it ready as soon as possible. Some delay has been caused by unavoidable circumstances, but League members may be sure no further delay will occur.

J. W. BEACH, *President.*

FROM DIRECTOR-GENERAL TRACY.

WHILE it is true that as the dental corps of the United States Army increases in numbers and efficiency the need for volunteer services on the part of the Preparedness League in connection with filling operations will correspondingly be reduced, it is not intended that the activities of the League shall be curtailed in this respect at present, as the accession of men from the new draft will be greater, both as to numbers and rapidity of induction than heretofore. It is, on

the contrary, absolutely necessary that greater impetus and effort be given to our work.

BRIDGE WORK.

It is also desirable that the scope of our work should be broadened to include the restoration of those registrants who are physically fit for general military service, and are held in group C solely because of their dental deficiency. A large percentage of these cases can be restored by the insertion of small bridges, thus bringing them up to the minimum dental requirements of six masticating teeth in occlusion and six incisive teeth in occlusion. No extensive restorations by bridge work are contemplated. In other words, only those cases are recommended for treatment which can be brought up to minimum requirements by the insertion of a small and inexpensive bridge.

At present there is no Government regulation compelling registrants in the class mentioned to have this work done at their own expense, and no provision exists making it possible for them to have this work done at the cantonments.

Most of the men mentioned above are anxious to be made dentally fit in order that they may be inducted into general military service and thus be of use to their country in the fighting line. I have found that with few exceptions the local boards throughout the country are very appreciative of the dental services rendered to the registrants under their control by the members of the Preparedness League, and I am sure if it is known that we have a large list of volunteer dentists who have offered to take cases of the type outlined above, a great number of registrants now standing in group C can be restored and immediately transferred into class 1-A.

It is, therefore, plainly the duty of every member to write to the League officer in charge of the work in his section notifying him that he will be glad to take one, two, or more cases each month, without expense to the registrant, the League, or the Government.

FAMILIES OF SOLDIERS.

Our activities should also embrace the care of dependent families of our soldiers, sailors, and marines, who are unable to pay for dental services. It has also been stated that one of the greatest possibilities for service on the part of the Preparedness League and its members would be a full and free co-operation between the League and the Home Service Section of the Red Cross.

In many instances the wives and families of soldiers in the U. S. army who have been accustomed to private dental treatment, but who, because of the reduction in their incomes cannot now afford to go to a private practitioner, should be taken care of by the volunteer dentists of the Preparedness League.

The Home Service Section of the Red Cross, through their authorized agents, will investigate each case as presented, and in those cases recommended for dental treatment at the hands of the Preparedness League the patient will receive a card bearing the indorsement of the Red Cross, stating that the patient is a member of a soldier's family and worthy of free dental treatment. In this manner much suffering can be alleviated and much dental trouble prevented among the families of the men who have gone forward to defend our country.

The medical profession is already co-operating most generously with the Home Service Section of the Red Cross, and it is hoped that every member of the P. L. A. D. will share in this work.

This type of work has already been begun by a number of Preparedness League units in various states, and the pleasure and satisfaction which the members are finding in taking care of these cases warrant us in believing that it can be extended to every state in the Union. Plans are now being formulated to take care of this new department in our activities and it is the intention of the officers of the League to have the work so arranged as to bring no special hardship on any one member.

While the Allied forces are meeting with gratifying success at the front and ultimate victory is assured, this is no time for relaxation in any of our war activities or patriotic efforts, and it is only by putting every ounce of human energy into action that the result desired by all truly civilized peoples can be attained.

As a national patriotic body of professional men we are strong and well organized, but in a few states the work has developed slowly, and it is urged that in such states the directors and officers grasp anew the great possibilities of the League's work and take up with increased determination the duties they have assumed.

Assuring you of my desire to assist and co-operate with you in every possible manner, I am,

Yours very truly,

W. D. TRACY,

Director-general for the U. S.

FROM THE COMMITTEE ON MOTOR CARS FOR CAMPS.

THE undersigned this summer visited Camp Greenleaf, which adjoins Fort Oglethorpe, Ga., and is some six or eight miles from Chattanooga, Tenn. Here are situated training schools for medical men, dentists, and others. It is with the dental training school, of course, that we are most interested. The dental corps at each military camp is badly in need of means of rapid transportation about the camp and to the neighboring city. Camps accommodate from 25,000 to 75,000 men; cities of that size would have trolley cars, cabs, and other means of transportation; moreover, there would be numerous shops. At a military camp there is but one place for procuring any needed article, and all such places are widely scattered. It is manifest that an automobile would greatly add to the efficiency of the dental corps at each camp, by saving time that would otherwise be expended in walking great distances. This is so true that many officers have purchased second-hand Ford or Dodge cars, but these being private property must be maintained at the officer's individual expense. Bills for gasoline, tires, repairs, etc., make large holes in an officer's pay check. This seems hardly fair.

The writer, therefore, conceived the idea that the Preparedness League should procure a car for Camp Greenleaf. On his return to New York he reported this to Director-general Ash, and was surprised to learn that a visit to Camp Upton had impressed Dr. Ash with the same need, and he was just inaugurating a campaign for obtaining funds for that purpose. The writer was then appointed chairman of a committee to foster this movement. Drs. Ash and Tracy sent out a circular appeal to the dental profession in New York, and through their generous response a Dodge car has been presented to the dental officers at Camp Upton.

The writer sent out a circular letter to one hundred men throughout the country asking for contributions to a fund to purchase a car for Camp Greenleaf. Before replies could have been expected to come in, the meeting of the American Society of Orthodontists convened in Chicago, and Dr. F. M. Casto, secretary of that society and an officer in the League, suggested that an appeal be made in open meeting for contributions. This was done, with a response that redounds to the credit, loyalty, and generosity of the members of that organization, not overlooking a few guests who were present: \$1131 was sub-

scribed, and paid in, in just thirty-eight minutes. A Dodge touring car was purchased by telegraph from a firm in Chattanooga, was promptly delivered, and is in use at the camp. A quotation from a letter of thanks received from one of the dental officers places this work in an aspect which is important, as follows:

"When the high officers of the camp see our car, and when the instructors in the Sanitary, Cardio-vascular, T. B., X-ray, Orthopedic, and other schools see it they know that the members of our profession are backing us for all they are worth and that we mean business. All such things serve to send dentistry higher and higher in the estimation of the men around us, and through these things to stimulate us, we hope, to drive so hard that some day when the old standards

of dentistry emerge from the war clouds, their colors will be flying high, and Uncle Sam and the whole world will turn to our profession and say, 'Well done, good and faithful servants.'"

The League may not be able to supply cars for all the military camps, but we are undertaking to furnish cars for at least ten more. We are at this moment awaiting the decision of the authorities as to which camps are most in need. As soon as these camps are selected, the state directors will be advised and asked to co-operate in collecting funds towards the car for the nearest camp.

After paying for the two cars already purchased and delivered, we are pleased to report that we already have a goodly sum left in the treasury of this fund.

R. OTTOLENGUI, *Chairman,*
Com. Motor Cars for Camps.

SPECIAL NOTICE.

Stenographers and Typists Wanted—Men and Women.

You are urged, as a patriotic duty, to enter the Government service in Washington, D. C., for important war work as stenographers and typewriters.

Women, especially, may thus aid in the nation's great effort. Men also are needed. Those who have not the required training are encouraged to undergo instruction at once.

Tests are given in 550 cities every Tuesday.

The Government maintains a list of available rooms in private houses in Washington and is erecting residence halls to accommodate thousands. Full information and application blanks may be obtained from the Secretary of the Local Board of Civil Service Examiners at the postoffice or custom-house in any important city.

JOHN A. McILHENNY,

President, U. S. Civil Service Commission,
WASHINGTON, D. C.

PORTIONS of an additional circular to Editors give the following additional particulars:

"In the matter of housing in Washington, it may be said that the Room Registration office of the District Council of Defense, at 1321 New York ave., has on its list more than 4000 rooms which have been carefully inspected and are available for new appointees. The usual charge for rooming accommodations with board, that is, the two principal meals of the day, is \$40.00 a month, but in order to obtain this rate two persons must ordinarily occupy one room. In addition, the Government will soon erect residence halls, including cafeterias, for the accommodation of Government employees in Washington. . . .

"It is perhaps unnecessary to say that an efficient civil service is as important as the armed forces in the prosecution of the war."

JOHN A. McILHENNY, *President.*

SOCIETY NOTES AND ANNOUNCEMENTS

NOTICES should reach the Office of the DENTAL COSMOS not later than the 11th or 12th of the month preceding that of publication.

The National Association of Industrial Dental Surgeons.

THE National Association of Industrial Dental Surgeons was organized at Chicago during the time of the recent meeting of the National Dental Association, with the following officers elected for the ensuing year:

President—DR. CARL E. SMITH, The B. F. Goodrich Co., Akron, Ohio.

First Vice-president—DR. W. A. BRIERLY, Colorado Fuel & Iron Co., Pueblo, Colo.

Second Vice-president—DR. G. L. EPLING, Pocahontas Fuel & Iron Co., Maybeury, W. Va.

Treasurer—DR. R. I. HUMPHREY, International Harvester Co., Chicago, Ill.

Secretary—DR. E. L. PETTIBONE, 6503 Detroit ave., Cleveland, Ohio.

Chairman Board of Directors—DR. THADDEUS P. HYATT, Metropolitan Life Ins. Co., New York, N. Y.

E. L. PETTIBONE, *Secretary*.

Northeastern Dental Association.

THE twenty-fourth annual meeting of the Northeastern Dental Association will be held at the Narragansett Hotel, Providence, R. I., on October 10, 11, and 12, 1918.

ALVIN A. HUNT, *Sec'y*,
Hartford, Conn.

Northern Illinois Dental Society.

THE Northern Illinois Dental Society will meet at Joliet, Ill., October 9th and 10th, 1918. A fine program and clinic is assured. Mark off the time now, and plan to attend.

E. L. GRIFFITH, *Sec'y*,
Freeport, Ill.

Susquehanna Dental Association of Pennsylvania.

THE fifty-fifth annual meeting of the Susquehanna Dental Association of Pennsylvania will be held at Hotel Casey, Scranton, Pa., October 9, 10, and 11, 1918.

GEO. C. KNOX, *Rec. Sec'y*,
300-301 Dime Bk. Bldg., Scranton, Pa.

Forsyth Dental Infirmary for Children.

NEW DEPARTMENT—LIBRARY AND MUSEUM.

THE trustees and director of the Forsyth Dental Infirmary for Children have authorized the creation of a new department, to be

known as the "Library and Museum." They solicit from the dental profession contributions of books and dental periodicals, particularly those out of print and not readily obtainable by purchase; also specimens of dental abnormalities, casts, or specimens of unusual structures of dental interest, for all of which permanent acknowledgment will be given.

FREDERICK A. KEYES, D.M.D.,
Librarian and Curator of Museum.

National Mouth Hygiene Association.

DEPARTMENT OF EXTENSION LECTURES.

A COMPLETE lecture set, consisting of full manuscript and thirty-six specially selected and prepared lantern slides covering the subject of Mouth Hygiene, is furnished by this association to members of state dental societies and others who may be considered as qualified to present the subject on the lecture platform.

For rental and sale terms and other particulars address the undersigned.

EDWIN N. KENT,
Director of Extension Lectures,
330 Dartmouth st., Boston, Mass.

Missouri Dental Examiners.

THE next meeting of the Missouri Dental Board for examining applicants to practice dentistry in Missouri will be held in Jefferson City, beginning at 8 A.M. on Monday, October 14, 1918.

For further information, write

V. R. McCUE, *Sec'y.*
Cameron, Mo.

Massachusetts Board of Examiners.

A MEETING of the Massachusetts Board of Dental Examiners will be held in Boston, Mass., October 21 to 25, inclusive, 1918, for the examination of candidates for registration. All applications must be in the hands of the secretary on or before October 11th. For further information address

GEORGE H. PAYNE, *Sec'y.*
29 Commonwealth ave., Boston, Mass.

Michigan Board of Examiners.

THE next meeting of the Michigan State Board of Dental Examiners will be held at the Dental College, University of Michigan, Ann Arbor, Mich., November 18 to 23, 1918, inclusive. Applications and other information may be obtained by addressing

B. S. SUTHERLAND, *Sec'y.*
Owosso, Mich.

Oklahoma Board of Examiners.

THE Oklahoma Board of Dental Examiners will hold their next regular semi-annual meeting at the State Capitol building, Oklahoma City, Okla., beginning December 9, 1918. Reciprocity only with Kansas, Missouri, Arkansas, Nebraska, Indiana, and District of Columbia.

For further information address

H. OVERBEY, *Sec'y.*
Ryan, Okla.

Montana Board of Examiners.

OWING to the present war conditions and the lack of a sufficient number of applicants, the Montana Board of Dental Examiners will *not* hold the usual January examinations. The next examinations will be held at Helena, Mont., on July 14, 15, 16, and 17, 1919.

T. M. HAMPTON, *Sec'y.*
Helena, Mont.

Illinois Dental Examiners.

THE next meeting of the Committee of Dental Examiners for the examination of applicants for licenses to practice dentistry in Illinois will be held in Chicago, the week commencing Monday, October 28th.

For application and further information, address the Department of Registration and Education, Springfield, Ill.

NOTICE.

The Department of Registration and Education of the State of Illinois has succeeded to the rights, powers, and duties vested by law in the late State Board of Dental Examiners.

The purely professional features of the dental law are in the hands of a committee, appointed from time to time by the director

of the department for this particular purpose. All of the administrative features of the law are handled by the Department of Registration and Education.

All correspondence in regard to applica-

tions, examinations, etc., in Illinois should be addressed to the Department of Registration and Education, Springfield, Ill.

F. C. DODDS,
Sup't of Registration.

No. 122,386, to MENTHO LISTINE CHEMICAL Co. Trade-mark for mouthwash and tooth paste.
No. 122,402, to GEORGE WINCKLER. Trade-mark for tooth, nail, hair, mustache, artists', clothes, and bathing brushes.

THE DENTAL COSMOS

Vol. LX.

NOVEMBER 1918.

No. 11

ORIGINAL COMMUNICATIONS

The Control of Focal Infections.

By C. H. MAYO, M.D., Rochester, Minnesota.

(Presented before the fiftieth anniversary meeting of the Dental Society of the State of New York, Saratoga Springs, N. Y., June 13-15, 1918.)

ALL life, from the standpoint of health and disease, is cell life. The chemistry of the world's activities is developed through the functional activity and protoplasm of the cell. The first forms of life, unicellular organisms, are lawless in their activities, multiplying without limit as food and environment is secured, and the stronger destroying the weaker. The normal type of microbe lives on the weaker animal and on the plant type of life, completing its existence from lack of food or the resistance of the host. It then dries into spore form, to again spring into action under suitable conditions. The lawless existence in unicellular organisms in contrast to multicellular life does not occur naturally. When the multicellular organisms appeared, true death entered the world. Under necessary control of growth and function through community existence, they became the prey of the unicellular organism. Man should not complain of the action of these organ-

isms, because through them occurs the evolution of the world, and the bad effects of certain germs under abnormal conditions may be far outweighed by the good they do.

If one considers the countless numbers of unicellular organisms, many so small as to require the highest power of the microscope to be seen, and many of whose existence we know and yet have failed to identify, it will be seen that, of these, few in proportion to the total number are destroying agents. The greater part of the disease germs are under the control of man's intelligence, if he has the power to enforce the preventive measures known to the world today. It is through such measures, applied in earlier life, that during the last thirty years the life of man has been lengthened a number of years. The microbes causing disease in man eventually bring about a stage of his life in which sudden death occurs from affections of the heart, brain, and kidneys, between the ages of fifty-two

and sixty-two years, as we have in no way changed middle age or advanced many more into old age. Death which is not accidental is due to the effects of the action of microbes—a result that may be acute and sudden, or chronic and slow in its termination.

The contagious character of various diseases has been appreciated for untold ages, and it has been known that certain of them developed some change in the individual which rendered him immune to a second attack of the disease. The first disease for which a vaccine was developed was that of smallpox, and while used in China and India long ago, it was first used in Europe in Belgrade, and was brought to the English-speaking people by the discoveries of Jenner.

A study of the blood in disease, as varying from its condition in health, and the action of its cells in developing antibodies, has been of wonderful value to mankind. Through this study, acute diseases that create an immunity are reduced in morbidity and mortality by increasing the resistance of the patient, as in tetany, typhoid, paratyphoid, typhus, yellow fever, etc. The innumerable diseases that formerly decimated mankind have been almost driven from the earth.

It is because of this wider knowledge of medicine that it has been possible to continue the present war without the enormous armies being destroyed by diseases which would long since have brought the war to an unsatisfactory termination.

We find, then, that there is developed in the blood stream, in acute diseases and fevers, an immunizing agent. On the other hand, with certain diseases there is, at some place in the body, a small focus of bacteria continually maintained, developing not an immunity but an anaphylactic reaction of the constant supply of microbes or microbe toxin instead of elevating the resistance of the patient against the germ. Such persons are subject to recurring colds on the slightest provocation, recurring neuralgias, recurring myositis, muscular rheumatism so called, lumbago, sore muscles

of the back and neck, etc., and it has been enough in the past for the patient to say he is subject to such trouble and for the doctor to make local applications and allow time to complete the cycle of improvement until, from any cause, lowered body resistance again reinstates the liability to an attack—and any part once affected by a microbe becomes more liable to repeated attacks.

We have also protein poisoning. Many persons are unable to eat various grains or berries, milk, fish, etc., which cause them to develop asthma or chronic diseases of the respiratory tract, or of the mucous membrane or skin, shown by local swelling, diarrheas, or eczema.

Although there are but few places in the body in which man quite regularly carries bacteria, they are always in the mouth, often in the tonsil and about the teeth in pyorrheas, alveolar abscesses, and buried crypts of tonsils. All tonsils that are capable of reacting to the infection and are of good size, 3 or 4 on the scale of 4, are usually not the cause of chronic disease but of strictly local involvement, and when inflamed temporarily, develop systemic disturbances. The position is most difficult for many physicians who have but recently come to a knowledge of the danger of a focus in these instances, not realizing that the blood stream is the carrier of the infection. In such cases the localizing trouble in the sciatic nerve or in the joint did not begin there, but arose from the existence of bacteria in a minute pocket, and if that pocket is under tension the disease is essentially chronic. The physician examines the throat and says the tonsils are not inflamed, or are graded 1 or 2 in size, and cannot be the source of the trouble. The dangerous tonsil is the one graded 1 or 2, without any effects of local inflammation on its surface.

Discarded teeth are often local foci of infection, and the X-ray has been of inestimable value in determining the presence of alveolar abscesses, absorbed roots of teeth, or absorbed bone about the roots. The findings are striking, when positive, but many pockets do not show

in an apparently good picture. The dangerous tooth is a crowned tooth, and if it is necessary, from the seriousness of chronic, recurring diseases which affect the heart, as a myocarditis, or the kidneys, or the joints or nerves, then small tonsils must be removed and teeth most carefully inspected, X-rayed, and, when diseased, extracted on the basis of symptoms, should they be of major importance. Endarteritis, overgrowth of bone about the joints, including the hip and spinal vertebræ, are also due to minor types of bacteria, which are probably in pockets not under tension. I have far less fear where nature loosely holds the bacteria; the dangerous ones are always under tension and in small areas, although we must now come to the acceptance of the fact that the blood of apparently healthy persons often contains microbes.

In our bodies, with almost no evidence of it, are living and growing the amoeba, the syphilitic spirochete in almost every place, the hookworm, and other germs too numerous to mention, and often temporarily doing no more harm than trout in spring water. We have wandering leucocytes with almost the power of animals to leave the blood stream, forage for material dangerous to life, and return to the circulation; and in many of us a little blood drawn and time given for culture will show some kind of microbe to be present. The stomach does not destroy all the bacteria taken into it; some may pass into the blood by the chyle duct, and probably more commonly enter the blood stream by way of the portal circulation but are destroyed in the liver. The germs in the mouth are carried on into the stomach, and in the great majority of persons there are numerous bacteria living in the gastric juice after all food has left the stomach. The dangerous varieties are those of the acid type, while those of alkaline nature are nuisances.

Of secondary importance to the microbe, from a biologic standpoint, is the chemistry of the fluids of local areas for their environment. This is similar

to the result from seeds planted or blown upon different soils. They may be planted to no purpose on the wrong soil, and they may be blown everywhere to take growth to advantage in proper environment. Bacteria carried throughout the body by the circulation are able to take up local growth only when thus carried to a given area. This accounts for the specificity of bacteria in their location causing acute and self-limited diseases, or chronic recurring or relapsing diseases. The acidity, the oxygen tension, and the condition of the general health, or local injury, may all be factors. Some forms will only grow in a certain place, as poliomyelitis in the brain and spinal cord, others in the sheaths of nerves, the first causing acute conditions, self-limited, and the latter, recurring neuritis. Thus we have rheumatism, appendicitis, gall-bladder inflammations and ulcers of the stomach, valvular diseases of the heart; in fact, nearly all of the local and general diseases of which we have knowledge are thus produced.

The factors of safety are largely within the control of man, in preventing diseases, and in the transference of immunizing resistant bodies, such as have been developed for the cure and prevention of diphtheria, typhoid fever, smallpox, poliomyelitis, and many other affections.

Diseases of middle life are increasing. They are microbic, of a chronic, recurring character and are carried into the blood stream from a few foci, the mouth being the source of greatest danger. A crowned tooth is not a crown of glory, and may cover a multitude of germs. Modern dentistry is relieving the world of much of its misery by watchful care of foci connected with the teeth, and the trend of modern medicine and dentistry is bringing their fields again closely together. Dentistry should be a department of medicine, as it is as closely associated with medicine as are the specialties of the eye, ear, nose and throat, etc.

Procain for Dental Operations.

By STEPHEN P. MALLETT, D.M.D., Boston, Mass.

(U. S. NAVY.)

(Read before the Virginia State Dental Association, Roanoke, Va., April 29 to June 1, 1918.)

IN these days, when our country calls upon each and every citizen to do his bit in the suppression of Prussianism, it is the duty of every dental practitioner to be fully prepared to render expert service.

The mills of progress must go on, even though a great many of our people are in some field of service. Those who are to carry on the work of maintenance, construction, and preparedness must not be burdened with unnecessary pain or trouble. The efficiency of a person, group of persons, or community can be seriously impaired by the ravages of disease or needless suffering, and it is within the province and duty of the dental profession to eliminate as much unnecessary pain as is consistent with present-day teachings. We can at least approach the ultimate ideal of a safe, painless oral operation, and it is an undeniable fact that in all time there has never been a better or safer anesthetic than the procain-suprarenin combination. Therefore we should all familiarize ourselves with this drug and its uses.

The new name, "Procaine," is under license of the Federal Trade Commission, in place of the old name, "Novocain."

As far back as 1853, experiments were conducted along the lines of local anesthetics, but for the most part they were unsatisfactory until Koller demonstrated the anesthetic properties of cocain, in 1884. In 1885, conduction anesthesia was first employed by Halsted, who injected the anesthetic in the vicinity of the inferior dental nerve rather than in the immediate vicinity of the tooth.

Braun, to whom the title of "father of modern local anesthesia" is applied, made the suggestion of the addition of the suprarenal capsule to the injecting solution.

I need not mention the danger of the use of cocain, because of its toxic effect. Procain fulfils the requirements of a safe and effective anesthetic, inasmuch as under satisfactory conditions it will permit the most delicate operations to be performed in peace and quiet, with very little hemorrhage, without haste or interruption, and with very little after-pain.

ANESTHETIC PROPERTIES OF PROCAIN.

Procain, which is seven times less toxic than cocain, occurs in small, colorless, and tasteless crystals, is soluble in water and less so in alcohol. It can be heated to 120° C. without decomposing. It produces the general alkaloid reactions and has the same effect on the peripheral sensory nerves as cocain. Procain creates no irritating effect upon the most sensitive tissues even when applied in strongly concentrated solutions, and no systemic effects are perceptible. It does not even affect the respiration, circulation, or cardiac function.

The 2 per cent. solution is the best for both infiltration and conduction anesthesia. With few exceptions, even in cases of anemia, neurasthenia, nephritis, arterio-sclerosis, heart diseases, or cases of general weakness, it is not found necessary to weaken the solution. The maximal dose is 0.5 gm. for subcutaneous

injections, but as much as 2 gm. has been used subcutaneously with no bad results. The maximal dose of 24 mils, or 12 syringefuls, of a 2 per cent. solution is more than is ever called for in dentistry. The U. S. P. IX has discarded the term "cubic centimeter" (abbr. Cc.) on the ground that the United States Bureau of Standards declared the term a misnomer, there being a slight difference between the thousandth part of a liter and a cubic centimeter. The word "mil," the first three letters of the whole word millimeter, has been adopted, and therefore in speaking of dosage I shall use the word mil in place of cc.

SUPRARENIN.

Suprarenin has great anemia-producing power and is a strong astringent. It is used with procain to contract the capillaries and tissues locally, in order to prevent absorption and infiltration into the soft tissues, thereby strengthening the anesthesia, and also to decrease bleeding in certain operations. It is more stable, keeps better, and is less toxic than any of the other anemia-producing substances. It is easily decomposed by free alkali, air, and heat. It is the strongest hemostatic and astringent known. For general use a solution containing 0.000,015–0.000,02 gm. of synthetic suprarenin to 1 mil (or a 0.0015–0.002 per cent. solution) is the best.

Therefore the combination of procain-suprarenin possesses the five essential qualities that a local anesthetic should possess to be satisfactory:

(1) The substitute should not be inferior to cocain in its anesthesia-producing power.

(2) It should be relatively non-toxic.

(3) It should have no irritating action even on the most delicate tissues.

(4) It must be easy to combine with suprarenin, and when so combined it should not lose its anesthesia-producing power; neither should it affect the action of the suprarenin, and it should be soluble in water.

(5) It must be unaffected by boiling.

The procain-suprarenin tablets are most suitable for our work. They are put up twenty in a tube, and they are sterile and reliable. There are three tablets on the market most suited for dental operations, viz, E, F, and T tablets.

Procain-suprarenin tablets E contain

| | gram. |
|------------------|----------|
| Procain | 0.02 |
| Suprarenin | 0.000,05 |

Procain-suprarenin tablets F contain

| | gram. |
|---------------|-------|
| Procain | 0.05 |

The combined E and F tablets with $3\frac{1}{2}$ mils of Ringer's solution yield a 2 per cent. solution. The T tablets also yield a 2 per cent. solution, and have the same amount of procain and suprarenin as the combined E and F tablets.

The Ringer solution contains

| | gram. |
|-----------------------|--------|
| Sodium chlorid | 0.50 |
| Calcium " | 0.04 |
| Potassium " | 0.02 |
| Distilled water | 100.00 |

Ten Ringer tablets to 100 mils of water, boiled for fifteen minutes, give the Ringer solution.

The apparatus consists of two Fischer syringes, one mounted in a short hub with a 26-mm. and the other in a long hub with a 42-mm. iridio-platinum needle. It is better to use iridio-platinum needles, because it simplifies matters in that they do not need to be boiled before using, can be used again, and are always mounted and ready. Iridio-platinum needles should be sterilized in the flame. They are easily sharpened by the use of a sandpaper disk. Steel needles are not so applicable because they break rather easily, oxidize, rust, and must be boiled just before using, which requires considerable time. However, because of the liability of needles to break off while injecting, I think it better to use steel needles for conduction anesthesia, because when broken off they are more easily removed surgically. A powerful magnet may be

used for removing them. The syringes should be held on a specially made stand in an all-glass jar containing alcohol. I have found that if extreme methods of cleanliness be employed, and any apparatus used be thoroughly cleansed and sterilized after using, a 99 per cent. solution of alcohol simplifies sterilization and is efficient. Two dissolving-cups, one graduated to 3 and the other to 10 mils, should be kept in absolute alcohol. The cups are made of porcelain and can be easily cleaned with dilute hydrochloric acid.

There should be one double-corked bottle for Ringer's solution.

Another jar should contain sterile distilled water in which to rinse the syringe and boiling-cup in order to rid them of alcohol. A glass tray in which to keep tablets, wires, wrench, reserve needles, syringe parts, and engine stones is also desirable.

Care should be taken not to handle the tablets, always replacing the cotton, rubber stopper, and cap immediately, otherwise the drug will deteriorate because of contact with air and moisture. If the solution turns pink it is contaminated and should not be used under any circumstances.

PREPARING THE SOLUTION.

Remove the syringe and cup from the jar and rinse all the alcohol off in distilled water. Fill the cup to the mark desired with Ringer's solution, and heat the solution to boiling. Add the tablets and do not boil, but pass through the flame to dissolve the tablets.

For normal cases: One T tablet to each mil gives a solution with

Procain2 per cent.
Suprarenin0.000,02 gm. to 1 mil.

For deep anemia: One E tablet to each mil gives a solution with

Procain2 per cent.
Suprarenin0.000,05 gm. to 1 mil.

For normal cases: Two F tablets and one E tablet to 6 mils gives a solution with

Procain2 per cent.
Suprarenin0.000,009 gm. to 1 mil.

The needle should be sterilized on the syringe in the flame, and the syringe is filled, carefully avoiding touching the needle.

REQUIREMENTS OF A SOLUTION PREPARED FROM TABLETS.

(1) The solution should be immediately used after it has been prepared.

(2) The solution should not come in contact with anything except the boiling-cup and the syringe. It should not be left longer than is absolutely necessary in the dissolving-cup nor in the syringe. The solution is very sensitive, being affected and chemically changed by heat, air, light, and especially alkalis.

(3) The tablets should be white, and the prepared solution should be the color of water.

PREPARATION OF THE PATIENT.

The operator must inquire as to the health of the patient and have a keen appreciation of the necessity of lessening the amount of suprarenin to be used.

In a few super-sensitive cases when the needle-prick is found to be exceedingly painful and annoying to the patient it is well to administer nitrous oxid and oxygen to the analgesic stage while inserting the needle. A pledget of cotton saturated with a 20 per cent. solution of procain (made from F tablets) and allowed to penetrate slightly into the mucous membrane will also reduce the pain of injection. With a very fine sharp needle in a small syringe one may inject a small quantity before the regular injection is made. Sharp needles lessen the pain of injection.

PREPARATION OF PLACE FOR INSERTION OF NEEDLE.

After placing a small napkin in the mouth about the field of operation, to catch any of the dropping solution, hold the lip away and wipe away all moisture possible. Then with a small pledget of

cotton dipped in a solution of aconite and iodine, equal parts, or campho-phénique, sterilize the part where the needle is more complicated than that of the the area to a small degree.

ANESTHESIA OF THE MAXILLA.

The nerve distribution of the maxilla is more complicated than that of the mandible. In the speno-maxillary fissure the maxillary nerve divides into the posterior palatal and infraorbital; the first enters the palatine canal and comes out through the larger palatine foramen, supplying the posterior part of the palate and the palatal part of the gum. The infraorbital proper passes along giving off branches through the infraorbital foramen, supplying the outside of the face and the labial part of the gum; the nerve then passes downward along the antrum, forming a plexus supplying the bicusps, incisors, and cuspid. The anterior superior alveolar branch emerges from the incisive foramen and supplies the anterior part of the palate and the palatal part of the gum.

The alveolar process of the maxilla is very porous, and although the porosity differs over the different teeth, yet it is sufficient to permit the infiltration method, as a rule. But one injection on the labial or buccal side is necessary, as a rule, for single-rooted teeth for operations in the pulp alone.

TECHNIQUE OF INJECTION.

Holding the syringe in the hand as one holds a pen, and with the opening of the needle directed toward the bone, insert the needle half-way between the gum and apex of the root, injecting and pushing the needle along until the periosteum is reached. Then slide the needle upward along the periosteum to reach a point a little higher and distal to the apex of the tooth; then inject slowly and evenly.

All of us have our own methods, but I want to say here that for infiltration anesthesia I have never known of a poor anesthesia or of undesirable results from

the so-called "puffing" by injecting. There is space enough between the periosteum and the epithelial layer of the mucous membrane for a considerable quantity of the solution, hence the "puffing."

After depositing 1-1.5 mils of the solution at this point, either remove the needle, or, if the tooth is multi-rooted, slide the needle distally toward the apex of the distal root, thereby using the same insertion for the full injection. Next insert the needle palatally about one-third of the way between the gum margin and the apex of the root, and when certain that the needle point is a little above the region of the apex of the tooth, inject about 0.25 mils of the solution.

It is well to massage the tissues after injecting, as it will quicken the process of absorption. Anesthesia takes place in from five to eight minutes, and lasts from twenty-five minutes to one hour.

ANESTHESIA OF THE MANDIBLE.

The nerve supply of the mandible is simpler than that of the maxilla. The inferior alveolar nerve, which supplies all the teeth, enters the mandible through the mandibular foramen and supplies all the teeth on one side of the jaw, anastomosing in front with the nerve of the opposite side. A branch is given off which emerges through the mental foramen and supplies the anterior part of the gum and the lower lip.

The inferior alveolar nerve, with the artery, lies before, and when entering the mandibular foramen *in*, the pterygo-mandibular space. This is bounded externally by the sulcus mandibularis, and internally by the internal pterygoid muscle. It is filled with connective tissue which readily absorbs the solution. The nerve lies posterior to the artery.

The lingual part of the gum and the side of the tongue are supplied by the lingual nerve. The lingual nerve first accompanies the inferior dental nerve, then passes farther forward and descends between the ramus and the internal pterygoid muscle at the anterior margin. It then lies half-way between the surface

of the oral mucous membrane and the inferior dental nerve.

The buccal nerve supplies the buccal part of the gum. It is also a branch of the mandibular division of the fifth cranial nerve. The bone in the mandible is much more dense, the outer plate being quite thick and having few pores.

For these anatomical reasons conduction anesthesia is better adapted to the mandible.

CONDUCTION METHOD.

A 2 per cent. solution for conduction anesthesia of the mandibular nerve is quite essential because of the large diameter of the nerve at the point of injection, and therefore the necessity of a strong solution to penetrate to the center.

TECHNIQUE.

Palpate the postmolar triangle with the tip of the index finger of the left hand and with the tip of the thumb of the right hand, with the remaining fingers held outside on the cheek, fixing the jaw. With a long needle (42 mm.) mounted on the syringe, and with the syringe resting on the teeth of the opposite side between the cuspid and first bicuspid, make an insertion into the mucous membrane at 1 cm. over the last molar, feeling for the internal oblique line with the needle just after insertion. Then slide the needle a little more medially and push it inward, keeping in close contact with the ramus. This may necessitate a different direction of the syringe according to the angle of the ramus to the median line, which varies. After the insertion of the needle, inject a small quantity of the solution. Then slide the needle along the bone until it is inserted about its full extent, depositing from 1.5 to 2 mils in the pterygo-mandibular space, in which the alveolar nerve and vessels lie. Anesthesia occurs from twelve to thirty minutes and lasts for thirty minutes, and sometimes for an hour and a quarter.

For purely dental operations we need

only to anesthetize the nerve which supplies the teeth. If anesthesia of the molars and bicuspid on one side is desired, then the mandibular injection alone is necessary. If all the teeth on one side are to be anesthetized, inject the mandibular nerve on that side and make the mental injection on the other, because of the anastomosis of the two nerves in the median line. For anesthesia of all the lower teeth use two injections, one over each of the mandibular foramina.

For surgical operations it is necessary to anesthetize the lingual nerve, which supplies the mucous membrane lingually, and the buccal nerve, which supplies sensation in the region of the first and second molar and second bicuspid. This can be accomplished in one injection if a sufficient quantity of the solution is used. Generally it is necessary to make a separate injection for the buccal nerve.

MENTAL INJECTION.

Insert the needle into the reflection of the mucous membrane just below the first bicuspid about half-way between the gum margin and the apex of the root. Push the needle downward and slightly backward along the bone for a few millimeters until about half-way between the two bicuspid. Feel with the finger for the mental foramen and inject about one mil and massage freely.

ZYGOMATIC INJECTION.

Palpate the zygomatic process of the maxilla, and, using a long needle, slide along, keeping close to the bone, going upward, backward, and inward, depositing the solution while injecting. In this manner the two posterior superior branches are crossed by the direction of the needle and anesthetized by the solution, desensitizing the molars and sometimes the bicuspid. It is advisable to inject in two directions to reach the superior alveolar branches. Inject two mils. The buccal part of the gum is anesthetized. Anesthesia occurs in about fifteen minutes, and lasts about one hour.

INFRAORBITAL INJECTION.

Palpate the infraorbital foramen and hold the finger on it. Retract the upper lip with one of the other fingers and insert the long needle into the canine fossa as high as the reflection of the mucous membrane allows, and until felt by the finger to be in the correct position. Inject slowly one mil, and press and massage with the finger to force the solution through the foramen. The incisors and cuspids will then be anesthetized. This injection is not advisable except in cases of abscesses or extensive surgical operations.

FAILURES AND ILL EFFECTS OF LOCAL ANESTHESIA.

There are failures and bad effects in all kinds of anesthesia. Local anesthesia today causes very little trouble in comparison to the failures with serious results of general and local anesthesia of past years. There are different sorts of failures: (1) True failures and ill effects. (2) Psychological effects. (3) Ill effects due to other sources.

CAUSE OF FAILURES.

- (1) No, or insufficient, anesthesia.
- (2) Undesirable symptoms during anesthesia.
- (3) After-effects.

When insufficient anesthesia is obtained, the operator is often to blame. Sometimes he may fail because of insufficient knowledge of the anatomy of the part or improper apparatus or technique, or because of inefficient drugs, or possibly because of too large a percentage of suprarenin.

UNDESIRABLE SYMPTOMS DURING ANESTHESIA.

Pain during injection may be caused by—

- (1) A solution which is too hot or too cold.
- (2) Antiseptic drugs unadvisably added to keep the solution sterile.
- (3) Solution non-isotonic with the blood.

(4) Injection into inflamed areas, such as an abscess.

In past experiences, in some cases I have found increase of heart action, sweating, or a queer feeling in the extremities, but since reducing the amount of suprarenin I have had no similar trouble.

In cases of tendency to fainting, tip the patient's head between his knees, give aromatic spirits of ammonia, strong black coffee, oil of camphor, or strychnin sulfate. Some of these agents should always be at hand.

Bromural is the most valuable preparation now used where sedative effects are desired. Bromural is administered in 5 to 15 gr. doses (1 to 3 tablets), regulating the dose according to the severity of the case and the vitality of the patient.

AFTER-EFFECTS.

Edema. Edema is a simple swelling caused by the infiltration of serum. It may be caused by solutions that are not isotonic, or by traumatism. Traumatism may be caused by multiple injections carelessly made, or possibly by directly injecting into a muscle. Edema, if no infection occurs, will disappear without treatment. The use of an ice-bag is sometimes indicated.

Psychological effects on the patient are largely controllable by the operator. Keep the patient's mind occupied and keep unpleasant things from his vision.

ILL EFFECTS FROM OTHER SOURCES.

Post-operative pain and inflammation may occur after an operation and may not be caused by the injection, but directly by the wound.

The causes may be—

- (1) Septic wound.
- (2) Wound infected during operation.
- (3) Wound infected after operation by the fluid of the oral cavity.

Trigemin, aspirin, and pyramidon are useful agents to counteract pain originating from injections.

Procain is useful in many of our most troublesome operations, such as cavity preparation, removal of pulps in almost

any condition, pulp stones, abscess treatment, and in diagnosis. It is widely used now in crown and bridge work for fitting bands, cementing bridges, grinding and devitalizing teeth. Extracting is made easier, and root amputations, impacted teeth operations, treatment of fractures, and removal of cysts, tumors, necrosed tissue, etc., may be accomplished under almost perfect conditions.

I strongly advise the use of the X-ray in connection with diagnosis and treatment, and at the same time wish to em-

phasize the importance of the realization that the X-ray is but an aid in diagnosis.

I have by no means exhausted the subject, but hope that I have explained somewhat the uses and methods of procain as a local anesthetic; and wish to urge all to take advantage of the use of this valuable anesthetic which is at our disposal.

400 MARLBORO ST.

[See also *Discussion*, as reported under "Proceedings of Societies," this issue.]

A Suggestion for Making Splints in Two Separate Parts and Their Union by Means of a Lock.

By ALPHONSE N. MOUFANG, D.D.S., Philadelphia, Pa.,

FORMER INSTRUCTOR IN CROWN AND BRIDGE WORK AT THE DEPARTMENT OF DENTISTRY,
UNIVERSITY OF PENNSYLVANIA.

MANY articles have already been published on splints and many suggestions have been given as to the quickest and the best methods of constructing them, but it seems as if necessity has aroused the profession to the desirability of finding some more practical method than any yet presented in order to do justice to our patients and to our profession.

The idea of casting splints was taken up and practiced in European countries about thirteen years ago, but it seems as if this method was not used on this side of the Atlantic, and nothing seemed to make its use imperative.

Dr. Aiguier has revived in the June issue of the DENTAL COSMOS the old but good method of casting splints, giving a detailed technique for the purpose; he does not, however, get away from the objectionable method of casting both splints in one piece.

If we wish to use cast splints we may just as well adopt the two-piece plan in making them, which is not only the quickest but also the most practical

method. I wish therefore to present a practical and at the same time very simple method of casting splints in two pieces, and one which can be easily practiced by all dentists.

Major Robert Ivy has approved the idea of casting splints in two separate parts and afterward uniting them by means of a lock.

A fracture case sent from the Navy Yard and treated at the dental department of the University of Pennsylvania was the first case on which the lock device was used, and it seemed to be very satisfactory.

TECHNIQUE OF MAKING THE SPLINT.

I shall first give a short description of the technique of making the two-piece splint, and afterward a few suggestions as to the technique of making the different locking devices. Necessarily the first step is to obtain good impressions and casts, to reconstruct the proper articulation, and to mount the casts on an articulator.

We next burnish heavy tin (3/1000 gage) well over the remaining teeth. Existing undercuts are taken care of by allowing the tin to extend straight downward toward the gums and not burnishing the tin into the undercuts, cutting the tin close to the gingival margins of the teeth. Next we use Kerr's casting wax and burnish two sheets of it separately over the tin. If there are spaces caused through missing teeth, these should be bridged over with wax to the level of the occlusal surfaces of the teeth.

The amount of wax to be used in bridging such spaces is of secondary importance provided a sufficient amount is used to allow the metal to flow into the bridged space during the casting process and insure strength to the splint. The bite will be opened through the use of tin and wax as pattern.

The proper articulation can easily be re-established on the articulator after the splints are cast and the necessary windows finally cut in the metal, if not already made on the wax pattern. The small tubes which are used as locks are made over a piece of round nickel-silver wire, gage 13 or 14. A small metal extension is soldered to each, giving greater retention space in the tube for the wire key. The extensions have small cuts on the sides and ends to further increase retention of the key. The tubes are waxed in position in such a way as to allow the key wire to slip in and out of the tubes without difficulty.

Before removing the wax-and-tin pattern from the model for casting, a piece of wax about $2\frac{1}{2}$ in. long and 1 in. wide is formed into a cylinder, one end flattened out and stuck with wax to one end of the wax-and-tin pattern at an angle of about 135° . Another wax cylinder of the same length but smaller in diameter is fastened with wax to the other end of the pattern at the same angle.

The thicker cylinder is used to make an opening in the investment through which to pour the metal, while the smaller one provides an escape for the air; it prevents air-bubbles in the metal and also enables the operator to accurately judge

the amount of metal necessary to be used in casting. When the metal appears at the surface of the smaller opening, sufficient metal has been poured. The angle of 135° for the inlet affords an easier flow of the metal during the casting process.

As to the investment material, bird's gravel and plaster, or sand and plaster in the proportion of 1 to 2 may be used with advantage. The ordinary vulcanizing flask, or a small tin box without soldered joints, will answer the purpose, being sure that the tin box or flask is high enough to include at least $1\frac{1}{2}$ or 2 in. of the two wax cylinders within the investment material, with about $\frac{1}{2}$ inch exposed as a free end. The investment material is mixed rather thin, the wax-and-tin pattern moistened, and the flask filled about half full with investment material; then the tin pattern is filled out carefully with investment material and is placed in the flask, flowing the investment carefully all over it to avoid air-bubbles, then the entire flask or tin box is filled up with the investment material.

As soon as the investment material begins to harden, cut some of it away from around the thicker wax cylinder, making merely a depression for the fusible metal which is to be poured into the investment from this side. Have the wax cylinders perfectly clean in order to avoid any investment material or foreign matter getting into the mold while the wax is burning out, thus leading to failure. The flask is then placed on the stove over a very low flame, allowing the investment to dry out. Increase the heat gradually until the investment is perfectly dry, and then use the blowpipe to burn out the wax, observing the same rules as apply in casting gold inlays. After the wax is perfectly burned out, the metal is melted and poured into the larger hole until it appears at the surface of the smaller one. After the metal is poured in the investment allow the flask to remain in the same position until it has entirely cooled down. Compressed air may be used in order to cool the flask more quickly, but not before the

metal has hardened on the surfaces of the pour.

Splints cast as suggested require little time for finishing. The metal surplus on the two ends is sawed off clear to the splint. A good rough stone, or better, a rubber file, is used with advantage, followed by sandpaper disks to remove all the scratches, afterward using a hard brush and pumice, followed by a soft brush and chalk. The finishing and polishing does not require longer than from twenty to thirty minutes.

The material used in making the splint is Babbitt's metal, or equal parts of tin and zinc. The use of pure tin would not be advisable, as it is too soft to permit attachment of the locking device.

There are many ways of locking the splints together, and it requires but a few minutes to choose a device which will answer the purpose in an especially difficult case. I shall give here the description of three different devices by means of which it is possible to open and close the patient's mouth after the splint has been cemented in position.

DESCRIPTION OF THE LOCKING DEVICES.

Fig. 1 shows an appliance for the upper and one for the lower jaw, both of which are cast. Each one has two small tubes on the buccal side, which are connected with the metal splint during the casting process. The two tubes of the upper appliance are placed in such a way that they fit in the intermittent spaces of the tubes of the lower appliance, forming one continuous tube when the jaws are brought into occlusion. The post over which the tubes were previously made and which exactly fits them is pushed into the tube, locking both appliances together as shown in Fig. 2. The post is bent at its mesial end downward and backward, forming a loop. This will enable the patient or dentist to secure a good hold on the lock if he wishes to open the splint; all that is necessary is to turn the small loop upward and pull the post forward. The

opposite side has, of course, the same arrangement.

The post, as marked on Fig. 1, can be taken out entirely. It is placed in this position merely to better explain how easily the appliance can be handled.

Figs. 3 and 4 show another device on the same model. In this device a tube

FIG. 1.

which was made over a piece of nickel-silver wire of gage 13 or 14, was used, after which the tube was opened, using a saw and cutting about one-third of the tube away, then filing away as much of the tube as was necessary to allow the wire to fit snugly in the half-round tube. Four of such small half-round tubes are used to form a lock. The tubes are

FIG. 2.

united to the metal splint during the casting process, and are placed in the manner explained in making the previous device. There is one point, however, that has to be especially borne in mind; that is, the floors of the four half-round tubes, two in the upper and two in the lower appliance, must be on the same level and placed in a slightly curved line forming part of a sector of a circle. The

post which closes the lock is bent on its mesial end in the same way as described for the previous device. The posterior

FIG. 3.

end of the wire is provided with a hinge arrangement which is fastened posterior to the last upper or lower half-round tube of the splint, allowing the post to move in the desired way.

FIG. 4.

It is advisable to attach the hinge arrangement on the opposite splint to the most distal half-round tube. The reason therefor is explained in its practical use. If the jaws are in proper occlusion the tubes will form one continuous half-round tube. All that is necessary for the

patient to close the joint is to press the post against the tubes, when, if properly made, there will be heard a little click, indicating that the post fits snugly and locks the appliance. In order to open the device the patient presses or pulls the loop buccally and the appliance unlocks.

Fig. 5 shows another device, which is nothing more than a lacing together of the appliance of the upper with the appliance of the lower jaw. Three small hooks are placed on each appliance in the

FIG. 5.

same way as the previous ones, with a wire attached by a hinge arrangement posterior to the last upper or lower tube for lacing the two appliances together. The device mentioned is so constructed as to enable the surgeon or dentist to open the appliance if for any reason it should become necessary to do so, but will not allow the patient to do so.

ADVANTAGES OF THE TWO-PIECE SPLINT.

The advantages of a splint constructed with such a device as I here suggest are the following:

(1) The device will enable the patient to open and close the mouth without any help in a case of emergency such as may occur during transportation on sea or land.

(2) The device will be of great value during secondary bone-grafting operations.

(3) The device will enable the surgeon or dentist to easily open the patient's mouth as may be necessary during the formation of a sequestrum on the palatal or lingual side of the jaw, in case of suppuration, laceration of the tongue,

the soft palate, or any other part of the oral cavity needing special treatment.

(4) Such an appliance would permit the application of any disinfecting solution desired.

(5) A splint constructed with such a

device would cause without doubt less mental depression because of the patient's being conscious that he can open the mouth if necessary.

The Conservation of Approximal Interspaces, Together with the Adjustment of Occlusal Relationships.

By L. ASHLEY FAUGHT, D.D.S., Philadelphia, Pa.,

PROF. OPERATIVE DENTISTRY, TEMPLE UNIVERSITY.

(Read before the Maryland State Dental Association, Baltimore, June 6, 1918.)

THE pathology involved in these operative procedures presupposes an intimate knowledge of the anatomy of the parts, and to make more effective what I shall say to you, a concise *résumé* is here made.

ANATOMY OF THE GUM AND ALVEOLO-DENTAL TISSUE.

I have never been able to become reconciled to the use of the term "gums," hence the use of word in the singular, to indicate an inelastic tissue characterized by hardness and immobility. With our thought directed to the approximal interspaces, we have largely to do with this tissue only as it rests upon the crests of the septi of the alveolar process. Its physiological import is defensive. Just beneath it and closely interwoven with it is that which I also prefer to speak of as alveolo-dental tissue rather than by the more usual terms of periosteum, alveolo-dental membrane, pericementum, etc. This is the tissue with which we shall be most concerned in studying occlusal relationships. It has a rich supply of bloodvessels and nerves. It is not a "membrane" in a strict histological sense, but is composed of fibrous and indefinite connective tissue. Its physiological im-

port is to transmit nourishment to the teeth, to furnish elasticity and a cushion under force, and to act as a sling in which the teeth are held.

NORMAL OCCLUSION.

The upper third molar occludes with but one tooth, the lower third molar, and it is to be noted that its mesial cusps both buccal and lingual practically so occlude into the curved occlusal surface of the lower third molar that with each closure of the jaws the mesial surfaces of both upper and lower third molars are held locked in apposition against the distal surfaces of their respective adjoining second molars. Assistance to this interlocking device is given by the fact that the disto-buccal cusp of the lower molar is thus surrounded by the four cusps of the upper molar. A careful study of this the normal occlusion of the third molars is most important, for it would appear to be Nature's plan that the upper third molar should stand as a bulwark in direct occlusion with its opposing third molar, held by the cusping of the lower third molar from springing away from the second molar, and thus retaining closed the interspaces of all anterior upper molars.

In normal occlusion the lower second molar does not occlude at all with the upper third molar, while the upper third molar, as we have outlined, so occludes with the lower third molar that with every closure of the jaws the mesial surface of the lower third molar is impelled forcibly against the distal surface of the lower second molar, thus preventing any springing backward of the lower third molar and the consequent opening of the interspace, this force being felt all along the line, keeping all the interspaces in the lower jaw closed against the invasion of any extraneous matter during the process of mastication.

Two other points of like import are to be noted. With all the molar teeth the mesio-buccal cusps of the upper occlude in the buccal groove of the respective lower teeth which oppose two-thirds of their occlusal surface to them; and the mesio-lingual cusps of the upper molars occlude in the central fossæ of the corresponding lower molars. The mesio-lingual cusp of the upper molar is thus surrounded by the four cusps of the corresponding lower molar.

Out of this *résumé* each must grasp the beauty, simplicity, perfection, and harmonious arrangement of Nature's design to give the greatest penetrating, crushing, and grinding force in the process of mastication, and the care and provision she has taken to preserve that effective functioning. Note, therefore, the relationships of the inclined planes of the cusps, the mutual support of all the teeth in the arches, and how the septal gingival fibers in the gum and the alveolo-dental tissue bind the teeth more firmly together in the mesio-distal direction and especially hold the contacts of the teeth tight; how the plane of the margin of gum septum in normal condition rises to the point of contact of adjacent teeth; how mucus is the only substance deposited on this soft tissue, and how everything else slips upon it and falls off.

A clear grasp and noting of these things should, without further comment from me, lead us one and all to conserve approximal interspaces and adjust occlu-

sal relationships when required; to be ever alert for the grinding of a cusp—an imperfect contour either occlusally or approxinally, a poorly shaped tooth, or a misplaced crown, may change the approximal contact point of teeth in the immediate vicinity. Any depression about a tooth makes a place for lodgment of food or calculus deposits, and these in turn encroach surely and steadily upon gum tissue and finally upon the alveolo-dental tissue.

The pathological conditions which thus arise are among the most distressing to which the mouth is heir. With the interdental gum band, which normally protects the alveolar septi, forced out of its proper relationship and broken and destroyed, hypertrophied flaps of its remains are left on either side of an approximal space, forming with the anterior and posterior teeth an open crater which soon seethes with decomposing material and infectious bacteria. Such is the descriptive picture of a condition more difficult to cope with successfully than even the most extraordinarily complicated case of dental caries.

IMPORTANCE OF PERFECT CONTOURS.

Perhaps a word further about imperfect contours occlusally and approxinally may not be amiss. For many years dentists have filled teeth with but a single idea—the insertion of a stopping into a prepared cavity of decay, with possibly some consideration of the effect of the material upon the tooth tissues. A few, more thoughtful than the majority, have now and then intimated that there were other considerations. I think Professor Flagg was one of the first to emphatically state that a gaging of the *right amount* of filling material inserted was most important. While naturally an excess on the occlusal surface would surely if not quickly be resented by the tooth, a deficiency might pass and not be noted, the *right amount* being always that which restores the original contour of the tooth at the point filled.

This is as true of the approximal relationships as it is of the occlusal; and

when the cavity in this direction involves cervical plus gingival lines it becomes a matter which if ignored gives rise to undesirable pathological states in the adjacent gum tissue. As many of the cavities which the operative dentist is called upon to fill involve the approximal surfaces and extend to these relationships, I may be pardoned for asking that more consideration be given to this portion of such fillings.

Every teacher of operative dentistry, with the thought of inculcating methods of procedure which experience has taught to be essential to prevent recurrent decay, will insist that the line of juncture between filling and tooth tissue here shall not be just above or at a line of contact with gum tissue, but shall in every instance be carried below the free-margin line of gum tissue.

Professor Black touching this point says, "In the treatment of all gingival third and proximal cavities it is an established fact that no decay begins, and there is no recurrence of decay, in any part of the tooth covered by a healthy free border of the gum. Therefore, in all of these cases the free border of the gum should be pressed away and the gingival wall so cut that its margin will be covered by it when it returns to its normal position." Every thought, you see, of the operative dentist is to make perfect fillings which in turn, by the use of proper technique, shall preserve tooth tissue and thus prolong the life of useful organs. Not a word is said, not a thought given to the fact that these organs can only be serviceable when proper care is taken of the alveolo-dental tissue. All other effort must fail if this point be not considered, and fillings thus made lead the operative dentist into the domain of pathology.

I have mentioned the importance of gaging the right amount of filling material, and perhaps should say that the evil influence is greatest when any portion of the cavity margin is left uncovered, for then in place of the mechanical and other irritations of over-fulness there is a more serious mechanical irritation, that of the sharp cavity margin and

the chemical irritation of disintegrating retained food magma and mucus.

Even when the right amount of filling material is used the pathologist has yet to consider the character of the surface of the filling material here placed to restore the lost normal state of healthy tooth tissue. I have noted that even when made faultlessly smooth there is an adventitious influence in the fact that it is filling material, the gum seeming to tolerate one kind more than another. I suppose that this is really true only in proportion as the material used has the capability of maintaining the faultlessly smooth finish.

GOLD FOIL RESTORATIONS.

So far as I know, gold is the only material possessing the quality of remaining placed, and that form known as non-cohesive gold the only one certain to continue indefinitely to reflect the painstaking work of the operator. With it can be produced a uniform solid surface and an adaptation to the cavity edge almost defying detection. The things which contribute to failure in producing perfect tooth form at this critical point in the filling are eliminated by its inherent qualities and capabilities, which beautifully lend themselves not only to the making of a perfect filling from the saving-of-tooth-tissue standpoint, but ever after from the pathological standpoint of being non-irritant to gum and alveolo-dental tissue.

AMALGAM RESTORATIONS.

Amalgam is not so satisfying; indeed, it is more than likely as the age of the filling advances, to become more and more troublesome in this respect. In dealing with amalgam as a filling material in these relationships, I am more and more impressed with the fact that the work is too frequently sloppily done, particularly in that portion of the filling which lies just below the gingivæ. In examining the work of others I have seen a great deal of this, as well as numberless instances where the filling was not

carried below the free margin of the gum, and the original condition has been such that the basal line of the filling was built roughly beyond the margin line of the cavity, producing at once the exact conditions of irritation.

This in a lesser degree will result where the amalgam either expands or contracts. It is very essential that great care should be taken in using this material to see that it is introduced by and with the aid of a matrix; and that the matrix, in its cervical relationships, should be precisely adapted to the cavity edge and immovably held in that position; so that when the amalgam is densely packed against the tooth tissue none of it shall protrude beyond the marginal line of the cavity.

Under the advanced conditions of manufacture, amalgam is becoming more and more a useful filling material. The chief difficulty in its use at the present time is the fact that the mind of the operator is predisposed to consider it as only a cheap filling material, and therefore he will not bestow upon it the care which it exacts in order to make perfect fillings. I do not make this statement in the spirit of criticism or captiousness regarding the operating methods of my brother operator, but because I am daily convinced that there is too much carelessness in this line of work, and I wish here to say something which shall at least tend to put a stop to this prolific source of irritation to gum tissue and to alveo-dental tissue.

Amalgam is not only to be thus studied by us in those cases where it is used as

a material for the entire filling of a cavity, but also in those other cases where its use seems to be called for especially, and where no other material is quite so available. I refer to those conditions in which, for many reasons, the tooth requires a plastic filling to be made with one of the various cements. My earnest conviction is that the cements have no place below the gingivæ; and that where their use is indicated as a filling material by the requirement of the case, this portion of the filling should be made with metal. The various amalgams naturally seem to be the most appropriate form of metal for this purpose, but should only be so used under the strict conditions of technique which I have just outlined.

Gutta-percha, though benign, yet by reason of its proneness to change its bulk is in the end a trouble-breeder.

The porcelain inlay presents alluring attractions to the operator as a material qualifying for just this desired service; but, to render this service, it must always be perfectly made and perfectly set—two requirements rarely met separately, and much less often obtained together, in the use of this material.

The plea which I am making here tonight is for the conservation of the health and usefulness of the alveolo-dental tissue, for, as has been very aptly stated by another, "A man in reality is only as strong as his peridental membrane."

MEDICAL ARTS BLDG.

[See also *Discussion*, as reported under "Proceedings of Societies," this issue.]

Dentist or Stomatologist?

By I. N. BROOMELL, D.D.S., Philadelphia, Pa.

(Read before the annual meeting of the New Jersey State Dental Society, Atlantic City, July 17-19, 1918.)

AS defined by the standard authorities, a dentist is one who devotes his time to the "treatment and replacement of the loss of the natural teeth."

A stomatologist is defined as "one versed in stomatology," and to the latter term is added as part of its meaning, "the sum of what is known about the mouth." The literal acceptance of the definition applied to a stomatologist is misleading, because it fails to carry with it any reference to the possibility of disease occurring in the mouth cavity, and the treatment of the same.

Practically all medical dictionaries, all medical articles and terms in the various encyclopedias up to this time have been compiled or contributed by medical men, who perhaps thoughtlessly have failed to grasp the full significance of the term stomatologist; so for our purpose we are compelled to coin a new definition, which shall serve as a foundation for the arguments to be included in this brief paper. From the viewpoint of the dental practitioner it is believed that the following would be acceptable as a definition for the term stomatologist: "One who devotes his time to the preservation of the health and the treatment of diseases of the human mouth."

In the care of the mouth the question might properly arise as to the dividing line between dental and medical practice. In other words, Where should the dentist leave off and the physician begin? In earlier days, and in fact not many years ago, this was not a difficult question to answer. The work of the pioneer dentist was extremely limited and clearly

defined, consisting in the extraction of teeth and the occasional application of a leech, and the actual cautery, as aids toward the alleviation of acute pains. This was sometimes accompanied by a crude attempt to replace lost teeth by mechanical means. With these as a foundation there was gradually developed a system of attempted tooth conservation which was the actual beginning of dentistry as a separate and distinct calling. From the more simple operations of filling, extracting, and inserting artificial teeth, there has been established a science which today stands as a most important factor in the conservation of the health, happiness, and comfort of civilized man.

The rapidity with which dentistry has advanced has been remarkable, but of all the important epochs in its history none can compare with the new relationship which has sprung up between dentistry and general medicine. Recent events have woven a fabric which will eventually bind these two professions into one harmonious unity of purpose, but that the best may come from this, progress must be made gradually and guardedly.

Nothing can do more to assist in this advancement than the willingness of the dental profession as a whole to assume the rôle of stomatologist, for by so doing we broaden our field of activity, and at once become masters of the situation, that is, the care of the human mouth. Much has transpired within the past few years to warrant such a move upon our part, and some of the more important of these may be related here.

The law passed on the last day of the last session of Congress and promptly signed by the President, places dental students on an equality with medical students, the former as well as the latter being permitted to enlist in the Enlisted Medical Reserve corps until they had completed their course and received their respective degrees. This was soon followed by a legislative enactment whereby a dentist could advance in army rank to the same extent as the medical officer. These actions soon resulted in the abolition of a separate dental and medical corps, by the inclusion of the former in the Medical corps, so that in the space of a few days the dentist in the army found himself advanced from a position of inaction and obscurity to one of signal rank, importance, and significance.

SYSTEMIC CONDITIONS AND THE TEETH.

While it may be claimed that the question of possible systemic disease through dental and oral infection was first agitated by a member of the medical profession, it is quite likely that the same thoughts had been brought out and possibly similar charges had been made by members of our own profession, this failing to make an impression chiefly because the author was perhaps less famous than Hunter, whose statements struck the popular chord. However this may be, it is an indisputable fact that, once being informed of its shortcomings, the dental profession has taken hold of the situation, deplorable and inexcusable as it may have been, and today we find ourselves working hand-in-hand with the physician to combat what in many instances heretofore appeared to be an unseen and misunderstood enemy responsible for no small proportion of human ailments.

Perhaps the most recent and the most noteworthy achievements to be eventually credited to dentistry are the investigations now going on to determine to what extent unerupted and impacted teeth are possible etiological factors in certain neuroses and epileptoid affections. Up to this time sufficient progress has

been made to warrant the belief that many of these conditions have their origin from teeth thus abnormally placed, as the removal of such teeth has in at least two cases been followed by a complete clearing up of the morbid state.

As we look about and note the demand for oral hygiene and tooth conservation by municipal governments, large and small, and when we witness the benefactions of such men as Forsyth and Eastman and note the results that are sure to follow the establishment and endowment of the magnificent institutions founded by these gentlemen, we are compelled to admit the arrival of a new and broader dentistry.

Again, when we note the significant fact that the average general hospital of today feels its service incomplete without the installation and maintenance of a dental clinic, and that corporations and business firms are providing for the care of the mouth among their employees, we are again compelled to admit the arrival of a new and broader dentistry.

And again, if we transfer our thoughts to the beautiful city of Cleveland and there see with our mind's eye a stately mansion transformed to serve the needs of the Research Institute of the National Dental Association, once more a new and broader dentistry looms up before us. And if, furthermore, we were to inquire into the nature of the investigations going on under the fostering care of this organization, we should be gratified to learn that they are stomatological and not merely dental in scope, and that they, too, are along the lines of a new and broader dentistry.

Still another indication of the extension of our field of activity is to be noted in the numerous cases referred to us by the physician—until quite recently an action almost unthought of.

These are some of the things that justify the argument that the time has arrived for the dentist to step aside and permit the stomatologist to take his place. It has been previously stated that this change must be brought about gradually and guardedly, because we must not lose sight of the fact that while the

work of the physician and the dentist has recently become much more closely allied, they must, for the present at least, remain separate and distinct professions. Until quite recently the average physician has regarded diseases of the teeth as relatively of such minor importance as to be quite beneath his serious consideration. Until recently, even as a consultant in cases of systemic involvement, the average medical man proved unsatisfactory because of his lack of knowledge of or belief in causative oral conditions, and showed a disinclination or possibly inability to suggest any treatment for a complication possibly purely dental or oral in its origin. Happily this state of affairs is now undergoing a definite change, and it may be truthfully asserted that at no time in the history of dentistry as a profession has there been such a need for the assistance and co-operation of the medical profession as at the present; and to this may be added the satisfying declaration that at no time has the latter, as a class, shown more willingness to accommodate the former in this way.

RELATION OF MEDICINE AND DENTISTRY.

While dentistry is not a fully recognized specialty of medicine, and while it cannot be so long as the course of study and methods of practice include mechanics combined with operative and surgical procedure, it is an unquestionable fact that medicine has a controlling and wholesome influence over its younger brother, dentistry, and on this account the best humanitarian results can only be attained by one harmonious unity of purpose.

Forgetting dentistry for the time being, let us proceed to consider the broader field of activity, and what may properly be included within this field. It is now a well-recognized fact that we no longer speak of dental (or tooth) prophylaxis, because this does not appear to serve the purpose; it is now "oral" prophylaxis. It may be said of the mouth as well as of the body in general, that the tendency is markedly toward the

prevention rather than the cure of disease. Recognizing the fact, therefore, that diseases of the mouth and teeth can best be controlled by prophylactic measures, this becomes the first duty of the stomatologist. The operative field of the stomatologist should include all tissues, both hard and soft, within the mouth cavity—the boundaries of which are, anteriorly, the lips; above, the hard and soft palate; below, the soft tissues forming the floor of the mouth, laterally the cheeks, and posteriorly that rather indefinite space, the fauces. As a conservative measure the question of prophylaxis is first to be considered. How shall we proceed, to keep the mouth clean or free from infectious material.

To accomplish this some method should be provided through which the mouth and teeth could be kept clean by personal attention. It would seem to be just about as inconsistent or ridiculous for one to depend upon the Turkish bath to keep the body clean as to be compelled to resort to the dentist to keep the mouth clean. It may be that the time is not far distant when the operation of cleansing the teeth will no longer be a detail part of our practice. But to bring this about, some radical changes must be made.

USELESSNESS OF MOUTHWASHES.

The writer is already on record as having some rather peculiar ideas about ready-made mouthwashes in general, ideas which in a general way make their use a questionable practice. In other words it is believed that the ultimate beneficial effect from the use of the average mouthwash is very much overestimated. The question comes to us frequently as to what mouth preparations are best and what virtue there is in these. It may be said that in the majority of instances a sort of stereotyped reply is made, without the varied pathologic possibilities of the mouth being taken into consideration, and disregarding the fact that a prophylactic which may prove of value in one mouth may be wholly ineffectual in another. The average ready-made mouthwash may be said to be just

about as effectual as a hair-restorer for the hairless head, or a magic ring for the cure of rheumatism. In making this statement the inference must not be drawn that there are no mouthwashes which contain the proper ingredients to make them act as they are expected to act in some certain cases, but their weakness lies in the fact that they are so promptly eliminated. In other words, they cannot be kept in contact with the parts upon which they are intended to act, for a sufficient length of time to be of any positive value.

There is need for improvement in methods covering oral hygiene and prophylaxis. The very fact that a clean tooth will not be affected by caries, with the equally significant fact that all teeth that are not clean do not decay, opens up a question for serious thought.

It might be stated with a good deal of certainty and without fear of positive contradiction that caries of the teeth is just about as prevalent in the mouths of those persons who give their teeth regular and systematic care as it is in the case of those who are totally indifferent in this regard. It may be that the question of predisposition and immunity is entirely responsible for this, and within certain limitations, inheritance, habits of life, diet, etc., are responsible for predisposition or immunity.

In making the foregoing statement, there is no desire to favor opposition to oral hygiene. Certainly the mouth, the gateway to the alimentary tract, should be kept free from unclean or septic material, and these remarks are therefore in the nature of a plea for normal conditions in the mouth, and if these normal conditions cannot be brought about physiologically or mechanically, then medicinal agents must be resorted to, and these should be compounded to suit each individual case, rather than to expect to find in any ready-made mouth preparation a panacea for all classes of mouth pathology.

APICAL INFECTIONS.

Perhaps the most important development in recent years, one which will eventually have much to do with trans-

forming dentistry into stomatology and is largely responsible for our scientific, medical, and surgical progress, is the much-discussed question of apical infection, and the influence it may have as a possible causative factor in systemic disease. It is not my purpose to discuss the possibilities of this subject, other than to refer to the important fact that the successful management of these conditions calls for the dentist to step aside and permit the stomatologist to occupy the center of the stage. To fully understand and successfully treat these conditions means much more than cleansing and filling the root-canal, an operation purely mechanical, or dental, in character. It calls for much broader consideration. The histology, physiology, and anatomy of the affected part must not only be considered, but the bacteriology, pathology, and methods of physiologic repair must receive attention sufficient to warrant an attempt at diagnosis and prognosis. Disease originating in the apical space may extend the field of observation and operation to parts in the mouth far remote from the primary causative factor, the tooth itself, so that the operator is compelled to practice stomatology in place of dentistry, to successfully manage the case. While the dentist might be content to accept a radiographic diagnosis in a case of suspected apical infection, and while he might be satisfied with one set method of treatment in all cases, the broader view of the stomatologist would possibly cause him to hesitate before accepting the radiograph as positive in diagnosis, until he had carefully considered the case from the standpoint of general pathology and bacteriology. This argument is intended to carry with it the belief that in no case of so-called "blind abscess" should a positive diagnosis be reached from a radiograph alone.

The writer is already on record with the statement that no small percentage of the "rarefied" areas shown by the X-ray are *innocent scar tissue*, containing nothing in the nature of pyogenic or other pathologic organisms, and that they should be left unmolested for the best physical welfare of the individual,

unless their diagnostic suggestion be corroborated by a bacteriological finding. The day has arrived—in fact, it never should have been otherwise—when the dentist or stomatologist should interpret his own radiograph, and perhaps in a large percentage of instances this is done, the radioscope now having become an important adjunct in our modern office equipment.

This possibility of systemic disease arising from tooth and mouth infection has had to a certain extent the effect of letting down the bars between medicine and dentistry, and will no doubt eventually result in transforming dental practice into stomatology.

While this is all well and good, we are at the same time compelled to take exception to the too frequent action of the physician—that, viz, of advising the extraction of teeth without dental consultation. Stomatology, or dentistry, whichever you may choose to call it, can no longer continue to be party to the wholesale removal of teeth simply because the physician advises their extraction. There is but one remedy for this unfortunate situation: it simply means the expression by the physician of a more substantial confidence in the dentist, and the nearer we approach the field of stomatology the greater this confidence will become.

DENTAL EDUCATION TENDING TOWARD STOMATOLOGY.

It is an undisputed fact that the past few years has shown a remarkable tendency for dentistry to broaden into stomatology, and much of the credit for this is due to the constantly increasing curriculum adopted by the dental colleges. Included in this are many subjects formerly thought to be of value to the medical students only, but now are recognized as an essential part of the dental course. By this means the average dental practitioner of today has fortified himself with sufficient medical knowledge to enable him to intelligently take part in the discussion of many general medical subjects, and more especially those which belong or are closely allied to dentistry. It is with much regret that

the same remarks cannot be applied to the general medical practitioner.

The failure of medical schools of the present day to instruct students even in the elementary principles of a branch of the healing art which the fathers of medicine did not disdain to teach, has long been regarded by dentists as a defect in the medical curriculum which should be overcome. While there can be no doubt as to the good results which might be expected to follow the adoption of the recommendation of the National Dental Association some years ago suggesting the inauguration of a course in oral hygiene in the medical curriculum, against such action will be urged the fact that the curriculum is already overcrowded and that the number of theoretical studies the student is required to pursue with more or less thoroughness, and the mass of technical detail in laboratory and clinical work which he is called upon to master, already tax to the utmost his mental and physical resources.

Great as is this obstacle to the inauguration in medical schools of a course in oral hygiene, prophylaxis, and fundamental dental pathology, room could doubtless be made for it, if it were deemed of sufficient importance, or were there any general demand for it on the part of the medical profession and the undergraduate body.

As a matter of fact, however, the interest manifested by medical students in dental pathology and associated subjects when taught in medical schools has never been of a very active or encouraging character. A few years ago an annual course of lectures covering that field, delivered in a prominent medical school by one of the most eminent dental teachers in the profession, was ultimately abandoned by him, chiefly because of lack of interest on the part of the students of the institution; and the course has never been resumed.

The fact that unhygienic conditions in the oral cavity are a prolific cause of grave systemic disorders can no longer be questioned, for it is manifest that the constant ingestion of septic organisms must in time overcome the resisting power inherent in healthy tissue and lead

to pathological changes more or less grave in character. These facts being now fully known to all well-informed physicians, it may be confidently hoped that even if overcrowded, room may soon be found in the curriculum of medical schools for at least the subjects of oral hygiene and prophylaxis. This being done, practitioners of medicine will be enabled to co-operate intelligently with those of the dental profession in their effort to arrest dental deterioration, and will be inspired to use all the weight of their potent influence with the community in support of measures looking to that end.

LINE OF DEMARCATION BETWEEN MEDICINE AND DENTISTRY.

The foregoing remarks are purely theoretical and problematic, therefore let us in conclusion consider the general subject from a practical point of view; and, first, as to the dividing line between medical and dental practice. If we continue to speak of a *dental* practice, then the line is clearly drawn. No physician would attempt to transgress upon the field rightfully belonging to the dentist. That is, he would refrain from filling, treating, or extracting diseased teeth. But suppose these diseased teeth are known to be the cause of some more serious condition in the mouth, and remote from them — into whose hands should such a case fall? Say, for example, through the persistent irritation of the tongue from contact with the jagged edges of a necrosed tooth, an epithelioma is developed. In such a case the dentist extracts the tooth, and the physician or surgeon operates upon the tongue. Or suppose the case to be the too frequent one of an external buccal sinus, originating, as these sinuses do in a vast majority of instances, from a pulpless tooth. In this case the dentist extracts the tooth, and if the sinus does not heal the patient is usually referred to the physician for further treatment.

Many cases of acute and semi-acute inflammation of the hard and soft palate, tonsils, and fauces have their origin in defective teeth, yet how often is a dentist called upon even to assist in arriv-

ing at a satisfactory diagnosis? Necrotic conditions of the maxillæ are perhaps in a majority of instances of dental origin, yet these cases are usually treated on the "fifty-fifty" plan, *i.e.* the dentist getting fifty cents and the surgeon fifty dollars.

While the modern textbooks on dental pathology all include as important the subjects of stomatitis and cancrum oris, it is the exception rather than the rule that the purely dental man attempts to treat these mouth conditions.

It is quite true that in many cases of facial neuralgia the dentist is consulted, with the result that frequently the seat of the trouble proves to be a tooth lesion, but if this fails to be the case, if an examination of the teeth results in a negative finding, back goes the patient to the physician or surgeon with the possibility of a resection operation as the only means of relief.

It has perhaps never been definitely decided, legally or otherwise, just what liberties or liabilities the degree D.D.S. confers upon one possessing this title. There is an unwritten law to the effect that a man to specialize as an oral surgeon must have first of all the M.D. degree, the ideal oral surgeon possessing both degrees, the M.D. and the D.D.S. This is doubtless due to the fact that in the past the dentist appeared content to confine his operations to the teeth alone, all other operations in the mouth being referred to the general surgeon. It is believed that there is an important place for the man who specializes as an oral surgeon, and the present war has proved this beyond a question of doubt, but there is no sound reason why the D.D.S. degree should not protect its possessor sufficiently to permit him to perform any operation in or about the mouth.

The one thing most likely to handicap a man having the degree of D.D.S. is the significant word "dental," and this part of the title will disintegrate just as rapidly as we choose to have it do so, by our recognition of a new and broader field of operation—the future degree conferred to be D.S. (Doctor of Stomatology) in place of D.D.S. (Doctor of Dental Surgery).

FLANDERS BLDG.

Nature's Tolerance and Compensating Adjustments as They Relate to Oral Restoration.*

(II.)

By JAS. KENDALL BURGESS, D.D.S., New York, N. Y.

(Read before the Maryland State Dental Association, Baltimore, June 5-7, 1918.)

AT a recent meeting of a state society there was shown in the progressive clinic a removable bridge, part of a system in which the burden of the entire perpendicular support of the bridge is placed upon the gum, the abutment teeth serving merely to hold the bridge in position. The system is based on the expressed belief of the clinician that Nature has not provided the human tooth with strength beyond that sufficient for its own needs, and that it is not wise or fair to place a greater burden upon it. This is taking a matter to which it has been my privilege to call attention heretofore, to the other and unwarranted extreme. It is an example added to many others of a tendency to circumscribed vision and shallow thinking which characterizes so many of our profession—for that matter, I presume, all professions—and it suggests to me the title of my paper, "Nature's Tolerance and Compensating Adjustments as They Relate to Oral Restoration."

A crying need of the dental profession—as, no doubt of all other professions—is for balance, perspective, the saving grace of a correct sense or estimate of relative values. We are prone to look at one thing so long and so intently that its image becomes fixed in the vision and interposes itself between our gaze and everything else to which our attention may be called. The average specialist or man with a hobby is like strychnin or atropin. He is tremendously concen-

trated and needs an immense amount of dilution before he is fit to be taken into the system of general practice. Common sense is all too rare a quality. We hitch ourselves to a theory, and lacking the ballast of a practical rationality it develops wings and soars away with us into the ethereal blue of an impractical idealism filled with all manner of inconsistencies.

Here, for instance is a striking example of inconsistency: A tooth well imbedded in the bony structures and formed and anchored for the express purpose of performing the function of mastication is considered not to be able to bear the burden of any additional service; so, by way of sparing the tooth, the whole stress of mastication by the restoration is put upon the gum tissue, which, in the very nature of things, was not designed to bear any of it. "Circumstances alter cases," and Nature has a marvelous way of adapting herself to circumstances. If she were intolerant and insisted on the absolute normal in anything, few of us would be here to tell the tale. But she probably has no established normal from which she has not departed and will not tolerate departure in some measure. Her compensations are matters of common knowledge and observation.

The deaf, for example, frequently acquire great facility in lip reading through exceptional development of the keenness and quickness of the sense of

* [This is the second paper of the series by the author on the fundamental principles of oral restoration. The first paper appeared in our September issue, at page 785.—Ed.]

sight, and so are able to converse almost or quite as well as if they could hear. The blind develop a wonderful sense of touch. I have seen one totally blind tell colors with great accuracy by feeling the objects with his fingers. These are conspicuous examples, but there are many similar instances of Nature's losses or impairments and her efforts at compensation. In truth, there are few organs or tissues that she has not been able at some time or other to dispense with or bear great alteration of, perhaps both in form and function, and to compensate the possessor for his loss by increased efficiency of some other organ or tissue.

What is true of the organism in general is true of the oral cavity and its environment, in which our concern is more particularly centered. So my friend the clinician is in error. The gum, which Nature probably never intended for the purpose of supporting man-made dentures, can adapt itself to the requirements within certain limitations if circumstances necessitate it. On the other hand there is no reason why a tooth with normal and unimpaired anchorage should not be able to take up a part of the burden of its lost fellow if the additional burden be correctly adjusted and within proper limits.

The question is: How far may we expect her to go in bearing these losses or modifications and the additional burdens they entail, what compensating adjustments may we reasonably expect of her, and to what extent and by what means may we be of aid to her in her effort to repair or compensate for the deterioration wrought by time and service, the ravages of morbid processes, or the damage done by violence or accident? And let us see if there are not some lessons we may learn from Nature and her attitude toward the perversions forced upon her and the destructive effort of her transgressors and despoilers, so that when operative interference becomes necessary we may act intelligently and as far as possible in harmony with her own plans and purposes.

First, considering the tooth as apart from its relations. Perhaps the most commonly met with transgression of Na-

ture's plan for the individual tooth is caries. It is a well-known fact that any disturbance even to the enamel is taken cognizance of by the pulp, which undertakes to protect itself by throwing out secondary dentin as a bulwark of defense against the encroachment of the enemy. Here is a very familiar example of Nature's compensating adjustment to conditions as they arise; and how successful she is in accomplishing it is attested in the experience of every practitioner who observes teeth retaining their vitality and health in many instances even though a considerable portion of their substance be destroyed by caries. Only less common are erosion and attrition, and the same tolerance and effort at adjustment to meet the altered conditions are constantly to be observed.

These processes, however, have small beginnings and are more or less gradual in the progress of their encroachment toward the pulp, and that organ, taking cognizance of their very beginnings, has opportunity in many cases to build up against the invasion, and gradually withdraw to a position of safety. The question has been raised as to the safety of the pulp in cases where the sudden removal of tissue by grinding and cutting becomes necessary in the preparation of teeth for bridge anchorages or abutments, seeing that the pulp is taken unawares and has not the same opportunity for protection.

RESISTANCE OF THE PULP TO OPERATIVE MEASURES.

In discussing the comparative danger to the pulp of the gradual process of decay and the sudden operation of tissue removal there are three things to be said relative to caries and the remedial measures for its correction. First: That penetrating the dentin far deeper than any operator goes in cavity preparation are micro-organisms which precede the actual breaking-down of tissue—at least to an observable extent. Second: That in removal of decay and cavity preparation there is also much sudden and precipitate removal of tissue just as there is in abutment preparation. Third: That this operation encroaches much

nearer to the pulp in many cases than does that for abutment preparation. If experience and observations have shown, as they have, that the pulp resists all these influences and encroachments and remains vital throughout the life of the patient, it needs only the application of common intelligence to force the conclusion that it will bear the strain of tissue removal by operative procedure. And there is ample data in the experience of every operator, who has cared to observe, to demonstrate that these conclusions are founded on facts.

There are some timorous souls among us, however, who are overburdened with a sense of responsibility for Nature's welfare, and fearful lest she be unable to protect herself. Being actuated by motives in kind with those of our generous-hearted and philanthropic birth-control specialists and advocates who would stand between God and a misused world to ward off His injustice and administer these affairs according to their own superior judgment—these pseudo-Solomons, usurping Nature's prerogative of death-control, destroy unoffending pulps at will, and because they adjust the rubber dam, sterilize the sword and the dirk with which the murder is committed, pack gutta-percha to the end of the canal, and take radiographs to show the mechanical precision with which every step of the assassination is conducted, they put on the virtuous airs of benefactors and talk learnedly of technique and asepsis.

The fact that all pulps are not equal to the increased effort and some of Nature's attempts at compensation and adjustment come to grief, offers no excuse whatever for the wholesale and indiscriminate slaughter of the innocents advocated and indulged in by these wise-acres to forestall the pathological process they claim always to foresee, but which, like most of our troubles, does not occur in probably the vast majority of cases.

Leaving the tooth as an individual for the moment, there is an interesting reciprocal relation of the teeth of which I desire to speak. A study of the teeth and their relations reveals the individual tooth as having a free single protruding

end of varying size and shape to meet Nature's requirements, and a single or multiple submerged end, as the case may be, imbedded and anchored in the bony structures of the jaw for retention and support, and that the free ends of the teeth in the opposing jaws bear a relation to each other which we describe as occlusion. These tooth-ends with their occlusal and anchorage relations have a direct bearing each upon the other, both as to tooth service and individual tooth welfare.

EXAGGERATED IMPORTANCE OF OCCLUSION IN BRIDGE WORK.

The chief function of the occlusal relation is the service of mastication, which in turn is the initial stage in the process of digestion. There is no doubt that in the normal occlusal and anchorage relations as Nature has planned them is to be found the highest degree of efficiency and the greatest compatibility with individual tooth welfare. The departure from the normal in occlusal relations, however, is so prevalent and so varied, frequently so aggravated and in so many instances never corrected, that we are forced to consider Nature's behavior toward these defective relations. If perfect masticating efficiency depends upon perfect or normal occlusal relations, it must be conceded that efficiency is reduced in the measure in which we depart from these normal relations, whether the departure be due to malocclusion or loss of the occlusal surfaces through deterioration or tooth removal, until in the edentulous mouth it ceases.

That Nature does not hold all of our organs and tissues to strict accountability, but gives much latitude in compensating adjustments, is patent to every lay and professional observer. It is no uncommon thing to see those possessed of disarranged or disorganized dentures, with impaired occlusion, or lacking any for that matter, retain full physical vigor and come to ripe age. So much for Nature's compensations in the case of occlusal relations and function.

When, also, we come to consider occlusal relations and individual tooth wel-

fare, we find the same tolerance on Nature's part—that whereas the stimulus to the teeth and tissues afforded by normal function of the teeth in normal occlusal relations is conducive, at least theoretically, to the highest state of tooth vigor, teeth in abnormal occlusion or entirely out of occlusion in many instances, retain their health and vigor in high degree. And these conditions pertaining to both systemic and tooth welfare, while not universal, are so frequent, so prevalent, that I am forced to the conclusion that of all the normal relations of the teeth the so-called normal occlusal relation is the least important.

No reflection is intended here upon the ideals and the splendid attainments of the orthodontist; but it must be remembered that he has an opportunity not vouchsafed to the worker in restoration. He is presented with a foundation intact, and his efforts are directed merely toward a rearrangement of that foundation. Likewise the prosthodontist, who gains all the support for his superstructures from the firm gum tissues overlying the bony structures of the jaw, has an equal opportunity to produce normal occlusion. But the bridge-worker is presented always with an impaired foundation. His problem is to ascertain the extent and character of its impairment, and the measure of proficiency inherent in its present status, and to provide for only so much service as that measure of proficiency is capable of producing.

Now let us come back to a consideration of our reciprocal tooth-end relations. Any occlusal relation that produces efficiency or service requires for that performance of service a commensurate stability or limitation of movement of the teeth, so that the free ends when brought in contact for function will glide against each other and not drag either tooth bodily out of its normal range of movement, a condition productive of trauma and a relation which we describe as traumatic occlusion. It is this stability or limitation of movement that gives the tooth its proficiency or ability to withstand the service of mastication—and this is the result, of course, of the relations of its anchored end, being em-

bedded as it is in the bony structures of the jaw. When this relation is interfered with and there is not left commensurate anchorage of the tooth, there cannot of course be sufficient stability to withstand the grinding of the surfaces of the occluding teeth against each other, and the dragging of the teeth out of the range of their normal movements, with consequent trauma and lessening of their proficiency, will be the result.

Here, then, is an interesting cycle in which is shown not only reciprocal occlusal and anchorage relations, but in addition a corresponding relation between tooth welfare and tooth efficiency. Upon the occlusal relations of the free ends of the teeth depends the welfare of their anchored ends, upon the welfare of their anchored ends depends their proficiency, and upon their proficiency depends the efficiency of their free ends, so that where the welfare of the anchored ends is impaired the efficiency of the free ends must of necessity be reduced. The fact that teeth are in so-called normal occlusal relations does not insure normal efficiency. The vital factor in tooth efficiency is not the relations of their occlusal ends, but tooth welfare as determined by the relations of their anchored ends. And this and proficiency are not necessarily fostered by so-called normal occlusal relations, which in the case of reduced anchorage may be productive of trauma, and trauma in the foundation is always absolutely and unequivocally to be avoided at whatever expense to the occlusion.

The relations of the free ends of the teeth is the established and pivotal point in the case as it comes to us, and the welfare of the anchored ends is the goal we must seek, the condition we must bring about, because without tooth welfare there can be no tooth efficiency. The welfare of the tooth is the measure of its proficiency, and its proficiency is the measure of its efficiency.

In those cases where restoration becomes necessary, it is plainly to be seen that we have no right to expect normal efficiency from minus proficiency, and we have no recourse but to fall back upon Nature's tolerance—which, as we

have shown, is an ample dependence. This we do by accepting the highest degree of tooth welfare to be procured in a given case as the basis of the operation, judging from that the proficiency of the foundation, and the establishment of such occlusal surface relations in accordance therewith as will produce only such degree of efficiency as is commensurate with the available tooth welfare and proficiency. Anything beyond this will be productive of trauma, resulting in impaired tooth welfare, reduced proficiency, and lowered efficiency, and this pernicious cycle will continue its destructive rounds until exfoliation results as the price we pay for our folly. So I repeat that we must aim at tooth welfare and depend upon Nature's tolerance of the frequently resulting and necessarily reduced efficiency.

We are familiar with the changes that take place in the shades of teeth as age increases, that Nature's harmony may be preserved. We note the ease with which the tissues of the oral cavity that so quickly discover and resent the invasion of a loose bristle from the toothbrush, learn to tolerate oral restorations of any size, even to the full dentures. And we know with what facility matters of taste and speech, and other functions of the teeth and tissues, adjust themselves to these new conditions—notwithstanding that one patient did refuse to pay for full upper and lower dentures because he was not altogether pleased with his efforts to "say 'success' successfully." These things need no enlarging upon, but I have laid emphasis on the relation between tooth welfare and tooth efficiency because I believe that our failures at this point have been the cause of many ruined dentures and wrecked opportunities.

ORAL SANITATION.

Passing on from the relations and functions of the teeth, we come to the care of the oral cavity. One of the matters that comes most frequently to our attention in the daily grind is that of the unclean mouth. It is interesting to us at this point because of the lengths to which some practitioners have gone

and are going to correct it and to establish so-called sanitation. It is well to inquire for a moment what is meant by the term "sanitation." If it means absolute and continuous freedom of the oral cavity from all the products of secretion and of accretion, it may as well be said once for all that it never can be maintained; few could survive the age of dentition! This must be patent to every observer of the oral cavity and its contents, of the forms and relations of the teeth and tissues, and of the uses to which they are put. It is true of the normal mouth—at least the nearest we find it, in this age of civilization, to what Nature designed it to be; and it is increasingly true in the measure in which we depart from the normal.

In view of this it is very evident that Nature expects and provides against some accumulations in the oral cavity. Her tolerance varies, no doubt, with the individual systemic resistance, which is influenced by many circumstances. What the maximum is, as revealed by the combination of advancing age, vigorous health, and oral uncleanliness that are wont to come under our observation, must be appalling to those of us who profess to believe that systemic prophylaxis lies in the way of perfect oral cleanliness.

We make a great to-do about unclean mouths, but there is serious question about the deleterious effects of loose food debris in the oral cavity. Some of the most unclean mouths to be observed are those of people in advanced years.

The profession has long nursed the fallacy that a clean tooth never decays. How shall we know? Was there ever, since the world began, a tooth that was always clean—if ever clean, for that matter? Certainly the degree of uncleanliness does not in any degree regulate the amount of decay we find in the mouths of our patients. Any uncleanliness that comes into contact with the blood stream is likely to contaminate it and is unsafe. But I am seriously of the opinion that very little pathological disturbance is traceable to mere accumulations of food debris in the mouth where any attempt at cleansing is maintained. The local congestion consequent

upon the accumulation of tartar about the necks of teeth far outweighs in importance the systemic effects of food debris in locations where it does not come into contact with the submucous tissues, and consequently with the blood stream.

It is not my purpose in this paper to attempt to establish any definite degree of oral cleanliness or lack of it as Nature's normal or the limit of her tolerance, but simply to claim that it does not mean sterility or absolute freedom from accumulations on the one hand, any more than it means unlimited filth on the other. And there is no reason why any sensitive soul should be shocked at such an admission. These are facts within the observation of every practitioner. The stating of them implies no carelessness in matters of oral sanitation, and to refuse to acknowledge them is merely to pose.

Those enthusiasts on the subject of perfect oral cleanliness who are engaged in the work of restoration do not hesitate to remove pulps and excise tooth crowns indiscriminately for the purpose of securing anchorage for removable bridges. Thus they rob Nature of her vital tissues, destroy functions and alter important relations with the rest of the organism—all in an effort to force upon her an unnatural freedom from extraneous matter, in the doing of which they endanger her blood stream—the supply conduits, where cleanliness is next to imperative and pollution may mean injury or death—in order to spare the alimentary tract, at least one function of which is that of the sewer! Here are shown again the possibilities of evil as a result of over-zeal for one phase of our effort. Instead of compensating for one disadvantage by offering a corresponding advantage, Nature is sacrificed in a very important direction, and the welfare of her whole systemic economy jeopardized to establish an immunity far beyond her needs and requirements in another.

If our productions are properly made and adjusted they will be as amenable to hygienic effort on the part of patient and operator as are the surroundings amid which they are placed. Nature will not expect or require more, and for

man to attempt it is a foolish waste of time and effort. There is no doubt that Nature has established a normal in conformation, arrangement, anchorage, and relations of the teeth and tissues of the oral cavity, and that tooth welfare, tooth efficiency, oral sanitation, and oral prophylaxis are all to be found in the largest measure in Nature's plan; but in many cases that come under our care there has occurred such radical departure from Nature's evident purposes as to make any possibility of realizing them a forlorn hope.

I protest that I am not callous to the needs and requirements of the oral cavity in respect to any of the matters concerning which I have written, nor careless in my efforts to obtain the best possible results commensurate with the difficulties under which we labor. Mine is an introspective effort to meet face to face conditions as they exist, to lengthen vision, broaden perspective, and by cultivating a saving sense of relative values to seek the greatest commensurate measure of proficiency and efficiency and avoid foolish and dangerous extremes and sacrifices that bring no commensurate compensating advantage. It has been the design of this paper to point out the un wisdom of fixing upon one object in Nature's plan, making a fetish of it, and sacrificing everything else that she holds dear and worth while to the accomplishment of that one object.

It should be patent to every thinking practitioner that all the interests of the teeth and tissues of the oral cavity, individual, relational, and functional, will be better served by following a plan of compensating adjustments so that no one part or relation or function or feature will suffer all the sacrifices, bear all the burdens, or receive all the blessings, but that there shall be a just and equable distribution among all the parts and relations and functions so that the highest average of welfare and efficiency may be attained and maintained. Thus will the systemic welfare, which is our highest concern and our greatest responsibility, be the better served.

The Treatment of Pyorrhea Alveolaris.

By C. E. HINES, D.D.S., Memphis, Tenn.

(Read before the annual meeting of the Mississippi State Dental Association, Meridian, April 16 and 17, 1918.)

CAN pyorrhea be cured? This question has probably been asked more frequently than any other ever presented to the dentist. It can be answered neither in the affirmative nor in the negative without qualifications. To the individual affected with this disease it is a vital question, and one that merits a conservative answer. No dentist has the right to answer this question until he has studied every phase of the particular case.

It should be explained to the patient that the word "cure" as applied to any disease is but a relative term. In pyorrhea it does not mean that the lost tissue, gingival, pericemental, and alveolar, can be restored, but it does mean that the teeth treated can be made healthy and comfortable. Teeth that cannot be restored to this condition should be extracted.

Whether or not pyorrhea can be cured in the above sense depends, first, upon a careful diagnosis; second, upon the dentist's ability to treat the case in hand; and third, upon the willingness of the patient to co-operate until results have been secured. In other words, it is a double personal equation, depending upon both the operator and the patient.

We should be careful in our promises to patients. As a rule, dentists promise too much. They promise this and they guarantee that, until the majority of patients want a promise that whatever is done in their mouths will last until they enter the "promised land." A truly professional man cannot promise anything except to do his utmost, and that "utmost" should always have as its prime object the conservation of the patient's

health. If we do this, we will get a new vision of dentistry. Dr. Price calls this new vision the "infection sense." When a dentist gets this infection sense, which is nothing but common sense, it changes the whole course of his thinking. He begins to look at the mouth from an entirely different angle. Things heretofore considered to be of small consequence assume grave proportions. He no longer tells his patient that an abscessed tooth is of little consequence, and that pyorrhea cannot be cured, but to just worry along with it until the teeth drop out.

Dr. Hartzell says that infection from the teeth and tonsils causes ninety per cent. of all heart disease; that fifty per cent. of arthritis and iritis is from the same cause; that kidney troubles are frequent from mouth infection. Cut these figures in half, and we would still have enough left to cause all of us to do some hard thinking.

Before entering into a discussion of how pyorrhea should be handled, let me say that the reason so many people who have otherwise had good dental attention have pyorrhea is because you and I have failed in our duty to use preventive measures when the opportunity presented. We have been content to clean teeth in a haphazard sort of way, overlooking lesions in the mouth directly responsible for future pyorrhea without making any effort whatever to correct them. We have laid little stress on the fact that it is just as necessary to thoroughly clean out the mouth once or twice a year and brush the teeth three times a day as it is to take regular baths and put on clean clothes. The public has

been taught to think that the cleaning of teeth is principally done for the sake of appearance, and that one dollar is a fair price for the effort. Yes, some of us have gone so far as to tell patients we would do their work for a certain price and not charge for the cleaning of the teeth. Is it not a shame that the most important and difficult operation in dentistry should be dragged in the mire in such a manner? I am free to confess that I have never yet cleaned a set of teeth to my entire satisfaction, even in a mouth apparently clean.

DIAGNOSIS.

The essential point in the treatment of this disease is diagnosis. Study, first, your patients: Determine whether or not they have enough pride in their make-up to really want a healthy mouth. Many people are so indifferent that it takes an open grave staring them in the face to move them. The best kind of patient is one that has been put through the third degree by his dentist. He usually has a broken and contrite spirit, and his mind is in a receptive mood for advice. He does not haggle over the point of whether or not pyorrhea can be cured, but is anxious to get the benefit of any treatment that will remove the infection from his mouth; more than that, he is willing to pay a fair price for the work. He has gotten out of the one-dollar class.

A thorough mouth examination should be given in a definite manner. Observe the mucoid plaques or films on the teeth. This is best done by using the staining solution formulated by Dr. Skinner of Chicago. Dr. Hartzell says this plaque or film contains 47 per cent. streptococcus viridans; that gingivitis is a streptococcus viridans infection. This emphasizes the importance of the plaque and of gingivitis in their relation to infections. It would seem that it is possible for a person to get just as much infection from this film on their teeth and from gingivitis as it is from any other source.

Observe the amount of salivary deposits on the crowns of the teeth.

Observe any malocclusion of the teeth. I believe more pyorrhea is caused or aggravated by malocclusion than any other one cause. Certain it is that no results of lasting value will be obtained until this condition is corrected.

Note all ill-fitting crowns and bridge work. The most hopeless case of pyorrhea to handle is one where the mouth is filled with crown and bridge work.

Note the condition of fillings as to contact, occlusion, etc., and all cervical cavities.

Radiograph devitalized teeth and all areas where deep pockets are suspected.

After all these conditions have been noted we are in position to make a more definite prognosis.

SURGICAL TREATMENT.

Treatment is then begun by polishing the crowns of the teeth. I am thoroughly convinced that the logical place to begin the treatment of pyorrhea is on the tooth's surface. The patient should be shown the amount of bacterial growth that has accumulated, and his attention directed to those areas which need the greatest daily care.

The next step is the removal of all salivary deposits. Any form of scaler desired can be used for this.

When this has been done we are ready for the true surgical procedure of removing the necrotic membrane around every tooth. This is a delicate operation and should be performed with great care. I am firmly fixed in my opinion that a scaler should never be introduced into a pyorrhea pocket. The only instrument to use is the file. Scalers scratch and etch the surfaces upon which they are used, while the file leaves a smooth surface, so desirable in this work.

After completion of the surgical work the mouth should be allowed to rest for at least two weeks. At the end of that time we are in position to observe the effect of our surgical treatment. The teeth should be thoroughly polished again with porte-polisher and orange-wood point. The contact points should be polished with tape coated with flour

of pumice. Then a final high polish with "carmi lustru" should be given. I do not hesitate to repeat the surgery wherever inflammation seems to be present.

I try to spend as much or more time on the polishing of the teeth as I do on the surgery. I rarely use the dental engine in polishing, but depend upon porte-polishers and orange-wood points and tape. I re-polish the teeth once a month or sometimes every two months, as the case may indicate. After we have seen a patient for a year in this way we are in better position to judge how often it is necessary to polish the teeth to keep the mouth free from disease. It is also to be hoped that after a patient has had the pleasure of having a clean mouth for a year he will be in a frame of mind to co-operate with the dentist in his future efforts.

I believe in the use of very few drugs in the treatment of pyorrhea, although I use drugs when conditions that warrant it arise. It can positively be said that drugs will not cure pyorrhea, though they have a very definite place in its treatment. In cases where the teeth have small gingival cavities and roughened areas I use a 10 per cent. solution of nitrate of silver; this I paint over the surfaces of the teeth. It is especially valuable where sensitiveness exists from instrumentation. It does not discolor sound tooth structure, but will produce discoloration where there has been disintegration. The persistent application of this remedy with frequent polishing of these areas gives better results than an attempt to grind or smooth them with stones.

Antiseptic precautions should always be taken before instrumentation for the removal of necrotic membrane. The mouth should be sprayed with a normal salt solution and the gums painted with some of the iodine preparations.

Pyorrhea patients should be taught to avoid the use of strong mouthwashes, antiseptic tooth-pastes, etc., and dentists should cease recommending them.

I instruct my patients to rinse their mouths thoroughly after each meal with

a mouthwash composed of a warm normal salt solution to which is added a tablespoonful of lime-water. Patients are instructed in massaging and in the Fones method of brushing the teeth. You must give the patient something definite to do and insist on its being done.

Fixed bridge work should rarely be used in a mouth affected with pyorrhea, the only exception being where small bridges are employed in the front of the mouth. There is just as much sense in cementing on a cork leg in an attempt to make it a permanent part of the anatomy as in cementing bridges upon teeth that have been affected with pyorrhea.

Dr. Rhein is authority for the statement that the English outlive the Americans, and that they do so in no small measure because the latter wear septic bridges in their mouths, while the former are less addicted to this possible source of danger.

The splinting of loose teeth is a failure. If a tooth cannot be tightened it should be extracted. This is easily proved by radiographing a case where the teeth have been retained by the use of splints.

The treatment of pyorrhea is a matter of detail and technique. The patient must be warned that periods of neglect will only result in disaster; that the greatest care must be exercised in keeping the mouth clean; that constant vigilance is the price of success. I feel sure that both patient and operator will feel amply repaid with the results obtained where a conscientious effort has been made.

DISCUSSION.

By Dr. WM. R. WRIGHT, Jackson, Miss.

Having been closely associated with the essayist during the greater part of his college course and for several years immediately following, I had a splendid opportunity to study the man and his methods. He has always been a close student, and he is never satisfied until he has studied his subject exhaustively

both from a theoretical and a practical standpoint. His interpretation of a given subject has always been practical. I want to commend the frank and lucid manner in which Dr. Hines has handled the subject of pyorrhea.

He gives the most practical ideas for the general practitioner that I have ever heard from a specialist. He has eliminated much of the red tape and high-sounding phrases that are often used, apparently to catch the ear of those who have paid little or no attention to the most prevalent and dangerous lesion of the human body.

My discussion will not be along the lines followed by the specialist, but rather from the viewpoint of the general practitioner who desires to serve a *clientèle* which is geographically and financially removed from the specialist's field of activities. In the beginning I wish to go on record as favoring the specialist in pyorrhea, when he can be reached conveniently, but the small-town dentist is deprived of this privilege, and we must shoulder this burden to the best of our ability.

Dr. Hines states that at least three things are necessary in the treatment of pyorrhea; correct diagnosis, skill of the operator, and co-operation of the patient. If these three points could be burned into the brains of every dentist in Mississippi today our stock would take a sudden leap upward. For a number of years my hobby has been to know an unsavable tooth when I see it. We lack the skill to properly scale and polish the necks of teeth, and we fail miserably to convince our patients that we really mean business, and therefore we do not get the

real co-operation which is so essential in the treatment of pyorrhea.

I cannot agree with the essayist in regard to medication. Personally I have never been lured very far by the clap-trap "quick cure" remedies; yet I have tried out almost everything that has been offered for a number of years, to see what value they might have. Each experiment has convinced me more thoroughly than before that the only real hope up to the present time is the thorough removal of deposits and necrotic tissues, followed by frequent polishing of the roots and necks of the teeth, along with the most approved prophylactic treatment. My experience has been that medication has worked along splendidly with instrumentation; it also furnishes additional interest for the patients by giving them more to do, and certainly assists in healing the gums.

A mechanical stopping to prevent reinfection of deep pockets has been of great value to me. I cannot appreciate the value of a two weeks' delay after surgical work is done. It seems to me that the patient would possibly lose some of the interest that had been aroused, and the operator would be misled by the false closing of certain pockets in remote places; however, this might be minimized in the practice of a specialist.

I had the pleasure of spending a day in Dr. Hines' office recently, when he showed me a number of cases that were under his treatment, each showing remarkable progress toward health. I believe Dr. Hines is doing a great work, and I want to again commend this splendid paper, and feel proud of the fact that the essayist is a Mississippian.

Classification of Tissue Conditions in the Mouth as Related to Efficient Dentures.

By SAMUEL G. SUPPLEE, New York, N. Y.

(Read before the annual meeting of the New Jersey State Dental Society, Atlantic City, July 17-19, 1918.)

LET us study together for a short time the tissue conditions as we find them in edentulous cases, with the thought in mind that these conditions can be applied to partial cases as well. We do not propose to talk only of the rare and difficult mouths, but to recognize the ordinary ones as well. An intimate knowledge of the conditions of the tissues of a mouth of which we are about to take an impression for an artificial denture will enable us to select an impression material; also to determine the amount of relief of the casts, the length of the plate, whether or not the tissues should be displaced or compressed; also to determine the strength of the muscular attachments, and the rigidity or plasticity of the mouths, all of which conditions have to do with an efficient denture.

By an "efficient denture" I mean one which retains its place in the mouth firmly and comfortably during all the ordinary acts, such as speaking and yawning, as well as mastication.

There are four fundamental principles which must be recognized and followed closely, for in so far as we depart from 100 per cent. accuracy in the application of any of these principles we lose just so much in the efficiency of the denture. These fundamental principles are the impression, the occlusal plane, the relief of the cast, and the articulation or interdigitation of the teeth. We might add another, "the area to be covered by the denture," or, as Dr. Wilson has termed it, the "extension for retention," which

should be considered while the tissue condition is under observation. This latter we shall refer to later.

While the form of the vault and ridges and the condition of the saliva may have some bearing on the final results, they are of minor importance as compared to the condition of the tissues.

Let us now consider some of the tissue conditions, that we may take up the first of the principles mentioned, viz, the impression.

I shall assume that you are acquainted with the other three, viz, occlusal plane, relief, and articulation, but we may have occasion to touch on them in the illustrations. We find we can divide the typical cases into four classes. (Fig. 1.)

THE FOUR CLASSES OF CASES.

In class I the vault and ridges are coated with an even layer of mucous membrane and connective tissue, and with muscular attachments rather high. Under these conditions the impression may be taken with any of the materials, such as plaster of Paris, modeling compound, etc.; in fact, by any of the methods that have been exploited in the last few years. In other words, the mouth will adapt itself to the plate.

In class II, commonly known as the "hard tissue mouth," we find the mucous membrane and tissue tightly drawn over the roof of the mouth and ridges, with the muscular attachments markedly strong and connected near the crest of the ridge with a hard bony prominence

along the median line. In such cases, plaster of Paris, or compound impressions with the mouth open, may be used with varying degrees of success.

Class III, commonly known as the "soft mouth," is one of the most difficult conditions we find, in that we have to discriminate between resilient and flabby tissue. The vault and ridges in this class are well covered with a thick coating of mucous membrane and connective tissue, with hard spots in different parts of the vault. The tissue may be either resilient or flabby. The muscular attachments are often very close to the crest of the ridge, and the whole outer half of the crest of the ridge seems to be movable. The technique, whether we need compression or perfect adaptation, will depend upon the tissue—whether it is resilient or flabby. The flabby tissue needs to be compressed. If the tissue is resilient, compression is contra-indicated. We find that the modeling compound impressions with the mouth closed, equalizing the bearing on the hard and soft tissues, are best adapted for this class of work.

In class IV we find the ridge in front, or some portion of it, to a greater or less extent soft and flabby. In extreme cases it is movable, almost like a second lip. Tuberosities may be either soft or hard, usually a hard area in the median line. The muscular attachments may be high or low. In this type of mouth we have to deal principally with proper displacement of tissue, including the ridges and tuberosities. We believe that, for this class of case, compound is the only material with which to take an impression to secure an efficient denture.

OBJECTS OF THE CLASSIFICATION.

The objects of this classification may be considered under three different headings:

First, to emphasize the importance of diagnosing the tissue condition and making a thorough examination of the mouth before advising the kind of denture to be made (whether metal or rubber).

Second, to indicate the material and

technique to be employed in taking an impression.

Third, to have a simple but complete medium by which we can convey to the patient the importance of advanced fees for certain types of cases, and why it is necessary for us to charge Mrs. Smith one price and Mrs. Brown another, for what on the surface may appear to be similar cases.

In this latter respect, I have found that many dentists are unable to give a logical reason, when contracting, and are charging advanced fees on the strength of the kind of teeth used, different colors of rubber, etc., whereas time, technique, and ability should be the fundamental factors.

It may be necessary to charge Mrs. Brown twenty-five dollars for the first plate, and then find the tissue conditions change materially within from two to five years, so that the fee for the second denture should be double that of the first. Many dentists have been placed in the embarrassing position of having made a very successful denture for a patient, by using the old-fashioned plaster technique, and after five years having the same patient return with all confidence to have another denture made. The dentist proceeds to use the same material and technique, only to meet with one failure after another, until the patient has lost considerable of the original confidence, and the dentist has begun to believe in mysteries, or that the patient is expecting too much of him. A careful study of the histories of changes in the tissue conditions will clear up these mysteries, and prove beyond a doubt that rubber dentures and improper articulation or occlusion may be the cause of all the difficulties.

The effect of rubber, in contact with tissue, will cause tissue changes in classes I and II cases sufficient to cause them to pass into class III within from two to five years. Improper articulation and a rubber denture will cause either classes I, II, or III to pass into class IV within a period of from five to ten years, and in many cases less.

To reverse the conditions, we find that by making a gold plate, properly articu-

Fig. 1.

UPPERS.—1. Muscular attachments connected high on the buccal and labial surface of firm ridges. 2. Vault covered with uniform layer of membrane. 3. Slight soft areas in rear third of the vault on either side of the median line. a. Indicates the end of hard palate.

LOWERS.—4-6. Muscular attachments connected low on the buccal and lingual border of the ridge. 5. Uniform layer of membrane over a prominent ridge. 4a-5a-6a. Indicate same conditions in the molar region.

Satisfactory dentures can be made from plaster or compound impressions in any form, whether mouth is open or closed. The length of the denture antero-posteriorly can be anywhere within $\frac{1}{4}$ in. of the edge of the hard palate, indicated by c.

(Technique No. 1.)

UPPERS.—1. Muscular attachments connected near the crest of firm ridges. 2. Vault covered with thin tensely drawn membrane. 3. Small areas of soft tissue in rear third of the vault, on either side of the median line. a. Indicates the end of hard palate. b. Bony prominence often present in the median line.

LOWERS.—4-6. Labial and lingual attachments connected near the crest of ridges. 4a-6a. Same condition in molar region. 5-5a. Firm ridge covered with thin tensely drawn membrane.

Mouths in class II require a small tray with mouth open or closed, using either compound or a combination of compound and plaster. Muscle trimming is an important factor. The denture must extend to the edge of hard palate, or as indicated by c.

(Technique No. 2.)

UPPERS.—1. Muscular attachments connected to the ridge through areas of soft tissue, 1a, covering the buccal and labial surface. 2. Soft tissue overlying the vault, varying in density. 3. Pronounced soft areas in the rear third of the vault, sufficiently yielding to be affected by muscles of the soft palate. b. A small bony prominence in the median line that is often covered with soft membrane and cannot be detected without pressure.

LOWERS.—4-6. Buccal and lingual attachments connected to the ridge through areas of movable soft tissue, 5-5a. 4a-6a. Same condition in molar region.

The best results can only be secured through the use of compound and "mouth closed" methods, equalizing the bearing on the hard and soft tissue when under biting pressure.

The edge of the denture at c must be just short of the vibrating (or movable) soft palate.

(Technique No. 2.)

UPPERS.—The predominant characteristics of class IV is soft ridge in front (3a), flexible tuberosities, or both. 1. Labial attachments may be either high or low, but connected to the soft ridge. 2. Soft tissue under the membrane may be thin, heavy, or varying in density. 3. Movable soft areas in rear third of vault may be small and shallow or large and deep. b. A bony prominence in the median line is often evident.

LOWERS.—4-6. Buccal and lingual attachments connected to ridge, 7, through soft membrane, 5. 4a-6a. Same condition in molar region. The soft ridge, 7-7a, is often thin (ribbon-like) and very flexible.

The use of compound to properly displace the ridges and tuberosities, the extension of the palatal border, and the equalization of bearing on the hard and soft tissues under biting strain are the essential points in class IV. The denture must extend beyond the hard palate, and embed sufficiently deep into the soft tissue at c to compensate for the droop of the edge of the denture when incising.

(Technique No. 3.)

lated, for a patient in class III (which is a difficult case) it will pass back into class I (which is a normal condition) within a period of less than a year. We also find that by making a gold plate for a class I case, within one year after extracting, and articulating the teeth according to scientific methods, the tissue conditions will remain the same almost indefinitely, except in patients of advanced years.

open will make little or no difference, except in the region of the rear third of the vault.

OPERATION FOR REMOVING A PORTION OF THE PROCESS.

Dr. Ruyl of New York has suggested, and in fact is producing some very remarkable results by, the removal of the outer plate of process over the buccal

FIG. 2.

The dark area in the buccal and labial border indicates the muscular attachments as well as the movable soft area. The black areas in the vault indicate soft tissue. The blacker the area, the softer and deeper the membrane. (1, 2, 3, 4 represent classes I, II, III, IV.)

In many instances, the anterior ridge in class IV lower is the only part that is soft. However, there are frequent cases in which the ridges in the region of the bicuspid and molars are thin (ribbon-like) and very flexible, whereas the rest of the tissue may be comparatively firm. This type of case must be considered as class IV, and the impression material should flow from both the buccal and lingual sides toward the crest of the ridge, which is the underlying principle for this class of case.

Mouths that have become abnormal due to migration of teeth constitute one of our most difficult problems, particularly in upper jaws, where the vault and ridges are covered with thin, tensely drawn membrane similar to class II cases, and the prominence of the gum indicates that the teeth must be abutted to the gum. This means that we reduce the area of contact and lose the advantage of having the periphery or rim of the plate embedded into the soft tissue of the buccal and labial border. In this type of case we must eliminate all compression and displacement of tissue; even an impression with the mouth closed or

and labial borders, by means of a simple operation, after which the most artistic results can be secured with pink rubber fronts, without showing any of the rubber.

Dr. Ruyl's method of procedure in these cases is to perform the operation when removing the teeth. If the teeth have been removed previously, he makes an incision along the ridge adjacent to the area where the bone is to be removed, denudes the process to a point below the line required for cutting off the process, and then cuts off the necessary bone with the bone-forceps. The edge of the process is rounded off with

an engine stone, and the gum flaps pressed back with the finger and thumb. These are cut off with gum scissors until they fail to meet *by about one-sixteenth of an inch*. Healing is allowed to take place, and in about four weeks an impression can be taken for any plate.

This operation usually reduces the height of the ridge, and the buccal and labial attachments will be decidedly movable and connected close to the crest of the ridge. This indicates that the case will fall under class II or III, depending on the condition of the tissues overlying the vault, but in any event much care and attention must be given to muscle trimming in taking the impression.

In some cases of the class IV type where plates have been worn by patients masticating on the front teeth only, excessive resorption takes place in that region; and the process in the bicuspid and molar regions indicates an enlargement or failure to resorb.

It would be impossible to put in a full denture and allow the cutting surfaces of the artificial teeth to follow the line of the occlusal plane. In order to establish a normal occlusal plane it would be necessary first to remove the hypertrophied gum and process in the molar region to a line where it would be possible to follow out the proper plane.

Then again, many times in the lower jaw the protrusion of the lower teeth is so great that it pushes out the process, making a protrusion of the lip and giving the appearance of a protruded lower jaw. Where an upper plate is required for such a mouth, it would be impossible to bring the teeth of an upper denture outside of the lowers, and the only way that an upper denture could be worn would be by allowing the upper teeth to strike inside the lower, thereby increasing the abnormal protrusion.

Cases of this kind must be treated surgically, and the mouth restored to normal, so that we can establish a correct occlusal plane, which, in addition to the proper impression technique, is necessary to the construction of the most efficient denture.

Inasmuch as this paper is intended to

bear especially on the classification of tissue conditions as related to efficient dentures, the impression material must be considered only in a relative manner.

IMPRESSION MATERIALS.

It must be recognized that plaster can be used successfully in classes I and II. The technique being somewhat simple, plaster is popular with the dentist for general use, regardless of the undesirability from the patient's standpoint, with the result that its failures are legion when used for making dentures for patients with tissue conditions as indicated in classes III and IV.

It has been the experience of the speaker that the great majority of the troublesome cases fall under classes III and IV, as will be shown later; and if the dentist will spend the time necessary to become so familiar with the manipulation of compound that he can solve the difficult ones, he will find that he can take short cuts in the compound technique that will save time, be pleasanter to the patient, and insure a greater degree of success than by any one of the modern plaster techniques.

Those who have not the time or the inclination to study compound may find it well to familiarize themselves with this classification, and use the simpler plaster or compound techniques for making dentures for classes I and II, and to refer their patients having class III or IV tissue conditions to those who specialize in prosthodontia.

With these thoughts in mind, let the illustrations be studied, as they show the benefit of this classification in making plate work more artistic and more profitable from the standpoint of the dentist, and more efficient from the standpoint of the patient.

CONCLUSION.

The very best results from plaster impressions are limited by the existing tissue conditions, while the value of compound is limited only by the ability of the operator in applying the proper technique to the class of case in hand.

1 UNION Sq.

The Influence of the War on Dentistry and Dental Colleges.

By S. W. FOSTER, D.D.S., Atlanta, Ga.

(Read before the annual meeting of the Mississippi State Dental Association, Meridian, April 16 and 17, 1918.)

MR. PRESIDENT, AND GENTLEMEN OF THE MISSISSIPPI DENTAL ASSOCIATION:

I HAVE been requested by your Executive Committee to speak of the influence of the war on dentistry and dental colleges. We all appreciate the fact that the great war in the throes of which we now are, and into whose vortex the great nations of the earth have been drawn, through the lustful ambition of an unscrupulous, selfish, and designing German monarchy for world dominion, has been the most brutal, mutilating, and destructive that the world has ever seen. Particularly is this true as it applies to the mutilation of the human face, that portion of the body with which the dental profession must deal.

It has been the means of putting the dental profession through a crucial test to which it has not previously been subjected. Dentistry has been given an opportunity to demonstrate its usefulness to humanity, and take its merited position among the learned and scientific professions, as never before during its history. The question naturally presents itself, Is the profession "making good"?

Realizing that there was a humanitarian call to duty early in the conflict, when the noble, courageous, though virtually helpless country of Belgium had been crushed, when every resemblance of honor and chastity had been ruthlessly cast aside, and the iron hand of German brutality was attempting to throttle all nations, and womanhood on every side was being outraged, noble men of our

profession answered "Ready!" And the work they have accomplished and are still carrying forward will not only, I predict, go down in history as among the greatest in the relief of suffering and restoring the human form, but as generations pass down the endless cycle of time their names will be written in the firmament in letters of gold, and stand out with the brightest luminaries, pointing those who may follow to still higher attainments.

When the war burst upon Europe in 1914, the position of the dental surgeon in our army was that of contract dentist. Today Congress has honored him with rank and emoluments equal to those of the medical profession. This recognition, which the dental profession has sought for in vain in the years past, has been given by reason of the splendid work done toward the relief of the injured.

The law provides for one dentist to every 1000 enlisted men, but the services of the profession as viewed from the standpoint of the army are of such importance that it has been recommended that the quota be increased to one to every 500 men. Nor has the Administration stopped there; they have recently organized a school for dentists in Oral Plastic Surgery, located at Camp Greenleaf, Chickamauga Park, Ga., this being the first school of the kind ever so organized. Having awakened to the importance of dental service from the standpoints of infection and prophylaxis, surgery, and prosthesis, our Government is

using every effort to increase the efficiency of those they depend on for such service. I am informed that it is the purpose of the Government to specially train at least 1000 dental surgeons in this school during the next twelve months.

What of the dental colleges? As a matter of fact, the dental colleges of the United States are virtually under the control of the army and the Government. The Medical Corps secured the passage of a bill, last October, permitting dental students who were drafted into military service to return to college and complete their dental courses before continuing active service. This was a special privilege granted because of the importance of the service for which they are qualifying. These men are enlisted in the Medical Reserve corps in inactive service. The freshmen just entering college are also permitted to enjoy the same privilege. The Government demands of the colleges special reports as to the standing and progress of such students. The War department requires an inventory of college equipment and general teaching facilities, and insists on a higher standard of qualification than has previously existed as a whole. They also reserve the right to deny recognition to a college and to transfer students from one school to another when in their judgment it would be to the advantage of the students.

Colleges which are progressive are today teaching oral surgery, treatment of infectious wounds, splints, wiring, bacteriology, sterilization, pathology, and physical diagnosis, to say nothing of anatomy, physiology, and chemistry, in a more general and comprehensive manner than in years past.

The college course has been increased to four years. The effect of this lengthening of the course has been to reduce the attendance in our colleges, but we feel sure that the higher quality will more than compensate for the lack of attendance.

Now, gentlemen, we can readily see from the foregoing that from this the most terrible of all wars has resulted the greatest recognition of dentistry, and

let us not forget that with this recognition come greater responsibilities.

We have been put on an equal status with the medical profession. This being true, we are expected to come up to the standard set by those with whom we are given equal rank. And, gentlemen, from the reports I have from Washington, it becomes necessary for the dentists of this country to take stock and strive to improve and merit this high standing, or we as a profession may fall more or less into disrepute. The bringing together of the dental and medical professions is going to prove one of the greatest benefits of the war, as well as increasing for us the respect of all.

Probably nothing has been of such benefit to both the medical and dental surgeons as the observations made in the prevention and treatment of traumatic infectious wounds. It has been learned that the interval of time elapsing between the injury and the operation, and the thoroughness of the removal of foreign bodies and dead tissue, are vital factors in the problem of infections of military wounds. We now know as we did not before that virulence of infection in traumatic wounds increases with the delay of surgical treatment. Traumatic infection of tissue is first confined to the exposed surface of the wound; and if a patient can be promptly treated, say within three to four hours after injury, it is possible to remove mechanically all sources of infection from the surface of the wound.

Our surgeons, both oral and general, have demonstrated as important factors in prevention of infection—1st, prompt surgical treatment; 2d, removal of foreign bodies; 3d, complete removal of devitalized tissue; 4th, the application of a germicide that will not delay the closure of the wound, and 5th, immediate closure of the wound when infection has been avoided.

However, it is not always possible to prevent infection. Splendid progress has been made with germicides. It is the consensus of opinion that the chlorin preparations have proved the most ef-

fective germicides. However, the standard preparations, such as Labarraque's and similar solutions, are found to be irritating to the skin. To overcome this condition, one of the most satisfactory preparations brought out was a dilute modification of Labarraque's solution known as the Dakin-Carrel solution, but it is so unstable that it is necessary to keep it almost constantly applied. The active chlorin is liberated very rapidly when applied to wounds.

Recently there has been produced a synthetic preparation by Dakin which he calls "Dichloramin-T" (toluene para-sulfon-dichloramin). This preparation is in the form of a powder, and an oil is used as the menstruum for dissolving

it. Eucalyptus was first recommended, but now chlorcosane (liquid paraffin chlorinated) is principally used. This will hold 10 per cent. of dichloramin-T in solution, but the usual strength recommended is that of from 2 to 5 per cent.; it must be kept in green bottles and in a cool place. It can be procured through Parke, Davis & Co. I mention this simply as an example of the progress which is being made in aseptic surgery.

As a result of the war, dentistry has been invited to occupy a position now in advance of what it could hardly have attained in twenty-five years. And, gentlemen, it is up to the dental profession to make good. Will we do it?

100 N. BUTLER ST.

The Relation of Nasal and Oral Sepsis to Systemic Disease and Surgical Conditions Resulting from Focal Infections.

By J. M. GUTHRIE, M.D., Meridian, Miss.

(Read before the annual meeting of the Mississippi State Dental Association, Meridian, April 16 and 17, 1918.)

AFTER reviewing the opinions and findings of others, I have come to the conclusion that the diagnosis of focal infection is often not a simple or easy matter, but in all systemic infections of obscure origin the nose, mouth, and throat should be carefully examined. The aid of the dentist and rhinologist will often have to be sought, and a skiagraph of the face and head may be required to locate the origin of the evil.

The treatment that offers the greatest measure of relief from nasal and oral sepsis is necessarily prophylactic. The physician must ever look on a "blind" oral abscess as he would on an appendix that is infected, a mastoid that is full

of pus, or a tonsil that is septic, and its removal should be effected, whatever may be the dental cost.

The problem with the dentist is not only to decide when he can save his patient from losing a tooth, but he must grasp the larger and more important consideration that losing a tooth may save his patient from a serious or possibly fatal infection.

A grasp of oral pathology and health conservation will be a greater asset to the dentist of the future than the mechanical skill that will produce a faultless inlay or preserve a devitalized tooth.

Billings declared that carious teeth are an inexcusable evidence of faulty

personal cleanliness in those who are otherwise healthy.

The rôle of diseased teeth in the causation of antrum trouble has long been generally recognized, but there are some other pathologic possibilities in abnormal teeth which have not received the recognition by the general profession that their importance would seem to merit:

Brandt has called attention to the rôle of diseased pulps in the production of suppurative inflammation in the nasal cavities.

Kallibay has stressed the part played by aberrant teeth and dentigerous cysts in the production of neuralgia in and about the nasal area.

Weeks has recently revived the question of causal relationship between nasal obstruction and dental malocclusion.

Pollock has reviewed the literature of suppurative perichondritis of the nasal septum resulting from alveolar periosteitic abscess of the incisors, finding eight cases, together with one of his own. He likewise found in the literature 106 cases of arthritis resulting from diseased incisors.

Baldwin has called attention to the rôle played by erupting teeth in the production of tonsillitis and earache.

Allport mentions myringitis, deafness, furuncles, and eczema as frequently resulting from dental disorders, and he urges the careful examination of the teeth in all cases of aural discomfort.

Bennett reports a case of obstinate deafness in a middle-aged woman from unknown cause relieved by extraction of roots of the second and third molars.

Scarlsbrick directs attention to the frequent association of enlarged tonsils with carious teeth in school children. He reports examination of some 4000 children, and concludes that enlarged tonsils are found with greater frequency in those having dental caries than those with perfect teeth. The incidence of enlarged tonsils is greater among children having many bad teeth than in cases with only two or three carious teeth. Marked enlargement of the tonsils is much more frequent even than moderate tonsillar enlargement among children with caries.

as opposed to children having perfect teeth.

Surgical conditions which result from a focal infection are often much more evident than the focus from which the infection arose. It is only recently that the importance of such foci of infection has been recognized and their treatment changed. Formerly, the lesion resulting from the infection was treated; at present, treatment consists, first, in searching out these foci and removing or draining them. The foci are often insignificant and difficult to find, especially when the symptoms produced by the extension of the infection are most marked.

MOST FREQUENT SEATS OF FOCAL INFECTION.

The foci considered the most probable source of infection which become surgical are, in their relative importance, as follows:

(1) The tonsil. The organisms may be lodged in the tissues of the tonsils, or there may be a small abscess between the lymphoid tissue of these situations which may easily gain access to the blood or the lymph stream.

(2) Alveolar abscess. This focus is often overlooked because it is very small. Oftentimes it requires an especially good roentgen-ray plate to make it manifest. It is difficult to realize that a small abscess at the root of a tooth may be the cause of systemic infection which may become very serious, though there are many cases on record in which such a condition has been completely relieved by the drainage of this sort of abscess.

(3) Infection in the integument, especially in the form of a boil or a carbuncle. When the systemic infection follows a boil or a carbuncle, the symptoms of the general infection usually develop about the time that the local condition has subsided, so that treatment in these cases consists in removing the distant infection.

(4) Several other regions—principal among which are the nasal sinuses, the ethmoid cells, and also the seminal vesicles. Many cases of gonorrheal rheu-

matism have apparently been cured by the drainage of the latter.

Infection in the lymph nodes in the cervical region is very common. In children the glands become swollen and tender, and sometimes suppurate. This condition is associated with enlarged and infected tonsils or infected adenoid tissue and teeth. Clearing the throat of these infections is almost immediately followed by the subsidence of the infection in the cervical lymph glands. Formerly scrofula was treated by opening and draining, and sometimes by removing these glands. This, however, will not be necessary if the infection in the throat is cleared up. But if the infection in the lymph glands does not subside after the throat has been freed of the infection it will be necessary to remove them, or they will become the foci of more extensive infection. Tuberculosis of the cervical lymphatics is not as common as it was at one time.

It is very interesting to observe the frequency of inflammation in the tonsils in patients suffering from exophthalmic goiter. The inflammation is often severe, and I have seen a number of cases go on to suppuration and quinsy. Many patients with exophthalmic goiter say that they have had repeated attacks of suppurative tonsillitis. Removal of the infected tonsils is important in the treatment of these patients, but we have not observed cases in which the symptoms of goiter were cured by removing the tonsils.

Surgical conditions in the chest which result from focal infections may be designated as pleurisy, empyema, and lung abscesses. These conditions more frequently follow pneumonia, which in itself is often the result of a focal infection.

In conclusion let me say, in the light of what is now known, that no physician can justify his action, or rather inaction, who, making a diagnosis of idiopathic arthritis, neuritis, or endocarditis, ceases further to investigate, and rests secure in blissful ignorance. Idiopathy is only a synonym of ignorance, and no physician

can afford to seek a refuge beneath its crumbling walls.

A FEW REASONS FOR TRYING TO LIVE LONG ENOUGH TO KNOW YOUR GREAT-GRAND-CHILDREN.

We of this generation consider ourselves pretty broadminded, but our great-grandchildren will think of us as narrow, unimaginative mossbacks. They will have the same sort of opinion of our outlook that we have of our great-grandfathers'.

Professor Loeb and other scientists already have taken important steps toward the discovery of the secret of life, but we cannot comprehend even now that in the time of our great-grandchildren doctors may know how to create life and keep the human machinery going after it has run down.

Neither would our great-grandparents have believed that by now physicians and dentists would cure "rheumatics" by treating the teeth or removing the tonsils, that they would transplant nerves, bones, and bloodvessels, make new jaws for wounded soldiers, and conquer the terrible and fatal "inflammation of the bowels" by removing the appendix.

It may seem far-fetched to us, but it should be perfectly true that, by the year 2000, disease will have been banished from the earth. Such a boon is no more impossible than was the idea, a hundred years ago, that by now we would have driven smallpox, yellow fever, bubonic plague, and typhoid from intelligent communities, and that the medical men of our time would find means to prevent lockjaw and blood poisoning.

Impossibilities have become accepted realities with such amazing regularity since our great-grandfathers' time that he is a brave man who would dare to predict that anything in human desire would be impossible by our great-grandchildren's day. The best we can say is that we are living in the most wonderful period of history so far. We cannot live to see the next century, but we can determine to live just as long in this one as possible.

Any excess or dissipation or carelessness which tends to shorten our life cuts off that much of our opportunity to see the wonders of the future. There never was such a poor time to die: never such a fine time to live. Each day that you

add to your life by careful living may mean that you see another miracle. Think of it in that way, and the simple rules which make for health and longevity will become golden commandments.

"Exodontia."

By B. A. BATSON, D.D.S., New Hebron, Miss.

(Read before the annual meeting of the Mississippi State Dental Association.
Meridian, April 16 and 17, 1918.)

UNDOUBTEDLY, exodontia is one of the oldest branches of dental procedure, if not *the* oldest. The history of our profession in every civilized country shows that the necessity for the extraction of teeth has been recognized from time immemorial.

A perusal of the history of this branch of practice, however, shows that but little advance in technique was made until comparatively recent times.

Among the English-speaking races, this feature of practice was given an impetus by the invention of the anatomical forceps by Sir John Tomes in the year 1840. Promiscuous "tooth-pulling" followed this invention. So prevalent, indeed, did this practice become that even within the remembrance of some of our older practitioners, the barber and the blacksmith in many localities were called upon to perform these operations. So short a period has elapsed since this evolution began that it is not unbelievable that such pseudo-operators exist even today in districts remote from dental influences.

The inevitable result of such unregulated practice has been in the past the unnecessary loss of many dental organs which, if given proper conservative treatment, would have again become useful members of the masticatory economy.

The rapid developments in the art of

prosthesis during the latter half of the past century were due in large measure to this indiscriminate tooth sacrifice. So prevalent was this mode of treatment for diseased teeth that inevitably, with the mass of the people, dentistry and "tooth-pulling" became synonymous terms, and dentist and tooth-puller became closely related individuals.

The influence of this propaganda is felt today even in our cities, and, as many of these procedures were carried on without the beneficent aid of an anesthetic, much of the present-day inherent dread of the dental chair may be attributed to these influences. It is probably true at the present time in many localities that some unnecessary pain and inconvenience is inflicted on patients.

The thoughtful minds in our profession today realize that the extraction of teeth is a surgical procedure pure and simple, and that it should be carried out on surgical lines, that surrounding sanitary conditions must be maintained, that sepsis must be avoided, that no pain should be inflicted, and that the early abuses incident to this operation must be corrected.

The spirit of the newer dentistry has developed specialists for these operations, and in dentistry, as in any other art, new discoveries and inventions demand

new terms and a development of language to measure up to these new conditions. Our nomenclature, therefore, has expanded, and where we formerly heard such bungling terms as "specialist in extraction," "I confine myself to the extraction of teeth," "I extract teeth only," "extraction specialist," "I do extraction," etc., the modern definition of this field is "exodontia," and the operator who devotes his efforts entirely to this specialty is termed an exodontist.

While these appellations are new, they are scientific in derivation and will live because of their correctness and because they lend a dignity to this field which before was lacking. It is equally true that what dignifies any one component part of our work adds to the dignity of the whole.

We are brought, then, to the exodontia of today, and a few words are apropos as to its practice and its bearing on the dentistry of tomorrow.

Being convinced of the general misunderstanding of the aims of dentistry on the part of the laity, and of the influence the extraction of teeth in the past has had in causing this misunderstanding, together with the realization that the apprehension of the dentist is due to operations in this field more than in any other, it behooves us all, whose future welfare hangs on the thread of public confidence, to aid in the correction of past abuses and to rectify former mistakes as we are competent to do so. In short, to quote Dr. Winter, "The sooner we become exodontists and practice exodontia, whether as a specialty or in general practice, the sooner will this condition be improved." The public is demanding more scientific service in this field, and organized dentistry must provide that service.

What, then, constitutes exodontia? is a logical conjecture. If we assume, as does the average layman, that every tooth is merely a tooth, and that an extraction is but the "pulling" of a tooth, we miss the mark, as does he. Exodontia, as we understand it, properly executed, means a successful surgical operation—an operation more dreaded by the

majority of people than any other, and one performed far more frequently than any other.

Among the elements making for success in exodontia, the first contingent must be an adequate anesthesia and absolute freedom from pain. Modern surgery demands this for two reasons: First, to facilitate operating; and second, to obviate shock. The latter consideration is by far the most important. Shock, as defined by DeFord, is a depression of the medullary centers controlling circulation and respiration, caused by too painful, too prolonged, too sudden, or too forceful stimulation of the afferent fibers, and is always accompanied by a lowered blood pressure.

ANESTHESIA IN EXODONTIA.

Accepting this definition, does not the vivid picture of outrages to sensitive nervous systems at the dental chair come to our minds?

The "tooth-puller" did not consider these sequelæ at all. Exodontia demands that, through its agency, shock, either psychic or physical, shall not occur if it is possible to obviate it. The choice of the anesthetic to be used must depend on the individual requirements of the case, the physical condition of the patient, the length of the operation, the accessibility of the field, the co-operation of the patient, and the operator's knowledge of his agent.

The accepted anesthetics *par excellence* today are nitrous oxid and oxygen and novocain. Individual requirements influence our choice. Somnoform is dangerous on account of its ethyl chlorid content, though useful in certain cases, while ether as a sequence to nitrous oxid and oxygen in hospital procedure for protracted operations is often indicated.

The general practitioner naturally has more use for a local anesthetic, and in this field novocain with suprarenin synthetic has rendered cocain practically obsolete. For the exodontist, conduction injections are rendering certain types of operations easy where formerly nitrous oxid and oxygen in the dental chair

militated against successful results. For routine work, however, nitrous oxid and oxygen is superior to all other known agents.

The modern exodontist realizes, too, that the removal of a tooth from its supporting structure alone does not constitute a successful operation in cases of sepsis. The thorough curettage of a chronically infected socket, which is now known to be so essential, is but a part of the exodontist's routine.

The preparation of the field of operation, the complete sterilization, the performance of the work under aseptic conditions as far as mouth conditions will permit, the dressing of the tooth sockets, and the attention to the physical condition of the patient—all are necessary details for the successful issue.

Before the advent of exodontia in its broadest sense, it is probable that tooth extraction was performed in a more haphazard manner than any other phase of our work. Methods of operating were the same as those of a decade previous. Even today probably more failures occur in the extraction of teeth than in any other operation undertaken by the average dentist.

Constructive dentistry has reached such a perfected stage that if any restoration is undertaken, it is known beforehand almost to a certainty what the outcome will be. Does the average dentist so regard the prognosis of his proposed difficult extraction?

There are many reasons why the outcome of an operation of this nature should be as certain as any other dental or surgical procedure. The causes of failure in any operation are usually attributable either to the difficulty of the work undertaken or the lack of skill on the part of the operator. In exodontia the former cause is due oftentimes to an incomplete diagnosis, and the latter to a lack of knowledge of the anatomy of the parts involved, a disregard of the pathological involvements, and insufficient operative dexterity.

Lack of manipulative ability, however, can seldom be laid at the door of the dental profession, but in undertaking serious extractions the former considera-

tions are perhaps at times overlooked. The large proportion of unsuccessful attempted extractions goes to prove that the difficulties are frequently underestimated. We must of necessity recognize the fact that the removal of teeth under certain conditions demands a degree of skill and a technique as perfect as in any other surgical operation.

A far greater degree of skill is demanded of us today than in the past. The teeth presented for extraction are usually in a broken-down state, few crowns are intact, impactions are frequent, fractured roots are common, and other abnormalities are present. Whereas fifty years ago at the first symptoms of trouble the tooth was removed while in a practically non-carious state, today the greater proportion are decayed almost beyond recognition and very frequently surrounded by pathologic disturbances. In spite of increasing difficulties to successful tooth removal, the public demand is for better service, and the demand is a just one. Unsuccessful operations react against the practitioner, even though he be not at fault. And not only is this true in the case of the individual, but this reaction also affects the profession at large.

We can closely estimate the number of patients lost to the dentist through unsuccessful extractions. And how many of these never again seek dental service of any kind unless driven by pain to do so? If the individual fails in a procedure as far-reaching in its advertisement, the whole profession must correspondingly suffer, for the effect of a failure is more far-reaching than is a successful result.

The query is often propounded, Should the general practitioner be a skilled exodontist? Our reply would be that he should be skilled in this as he is expected to be in any other operation which he undertakes. Whether in exodontia or any other phase of practice the question revolves around this other question, "Is the patient entitled to the best service obtainable?"

While I thoroughly believe in exodontia as a specialty, I also believe that the general practitioner should be skilled

in exodontia if he includes that class of operations in his practice. Many general dentists do not desire to extract teeth, many are called upon to do so even against their wishes; all dentists occasionally meet cases which could not be referred if they so desired. These demand attention, and even if simple cases, they deserve the best of care.

Probably in no line of his endeavor has a dentist such a rare opportunity to pave the way to a patient's confidence as in a skilful extraction performed under the right conditions.

During the future years exodontia will play a greater part than ever before in the oral hygiene propaganda. These two fields lie close to each other. No longer is it good practice to leave a diseased tooth in an otherwise clean mouth. Per-

fect mouth sanitation demands the removal of these infected foci. When the oral hygiene movement shall have reaped its deserved reward it will be found that modern exodontia has played an important rôle.

In conclusion, we believe that the scientific extraction of teeth is but in its infancy, and the future years will unfold much for the betterment of the race, but in the meantime it behooves us all to practice exodontia, and not "tooth-pulling"; and let us, whether specialists or general practitioners, live up to the best teachings of our period. Then we shall each do our part toward making exodontia a worthy part of the great fabric of dentistry which is destined to do so much toward the alleviation of human ills.

The Arrival of the Dentist.

AMERICAN RED CROSS.

American Red Cross workers are so popular in the neighborhood of this hospital for refugees near Lyons that the repatriate children even welcome the arrival of the dentist with his instruments. However, by means of pictures, magic lanterns, movies, charts, and exhibits, these little folks have learned the importance to France of keeping their teeth in good condition, and like their fathers, are ready to serve France even if it does hurt.

PROCEEDINGS OF SOCIETIES

Dental Society of the State of New York.

Fiftieth Annual Meeting, held at Saratoga Springs, N. Y., June 13-15, 1918.

(Continued from page 927.)

THURSDAY—*Evening Session.*

The meeting was called to order at 8.30 o'clock, by the president, Dr. Rich.

CHARLES H. MAYO, M.D., of Rochester, Minn., was expected to be present in person to read his paper entitled "The Control of Focal Infections," but sent a telegram stating that military duties prevented his attendance. His paper was read by Dr. A. L. Swift, of New York City.

[This paper is printed in full at page 963 of the present issue of the DENTAL COSMOS.]

DISCUSSION.

Dr. M. L. Rhein, New York City. The size of the audience present to listen to Dr. Mayo's paper is the strongest evidence of the impression that has been made upon dentistry in the past few years by this subject. Surely all of us here tonight realize the impossibility of any audience of this size being interested in this subject a decade ago.

What I have to say on this subject is purely of an impromptu nature, and I trust you will accept it in that way. In considering the subject of focal infection, there are two methods by which the toxins from these infections are carried into the system, *i.e.* either by continuity and absorption, or, as Dr. Mayo has said, carried to a distant part through the circulation—the blood, or the lymph, or the chyle, whichever it may be.

The question of the control of focal infections is unquestionably a very practical one, as far as it concerns dentistry. The question is, What are we, as dentists, to do under the circumstances? Dr. Mayo has divided the subject into two phases, one preventive and the other curative—a division that is undeniably the best that we could make. There is not a point in the splendid paper to which we have just listened that I can imagine exception being taken to. Of all the essayist has said, the most impressive thing to me was his reference to the subject of the prevention of focal infections. This is no new topic to dentists; it is almost as old as dentistry itself, and it is the one thing that we ought to give the greatest attention, in order that the coming generations shall be brought up in such a way that focal infections cannot take place, which means that there shall be no devitalized pulps—because, when you analyze the subject, it rests there.

I was particularly impressed by the division the essayist made when he spoke of abscesses. Personally, I prefer to divide this subject, in treating of its symptomatology, into abscesses and what we were formerly accustomed to calling "blind" abscesses. The essayist divides them into those in which the bacteria are loosely held, as against those that are under tension, and he speaks most forcibly of the greater danger of those in which the bacteria are under tension.

The ordinary alveolar abscess is one where we have suppuration, where the toxins are germinated from the pus, and are not under tension. Nature has already started in to play the rôle of doctor to cure the patient. The pus finds an outlet in the mouth, and is swallowed, and to a certain extent this action is nullified by the gastric juices. The alveolar abscess is comparatively harmless as compared with the "blind" abscess. Dr. Mayo has noticed this clinically, and it is entirely in accord with all we have noted in the literature on the subject. In the "blind" abscess we have no suppuration. We have the colonization of bacteria, locked in about the roots at the ends of the teeth, and during mastication and the movement of the teeth we get the tension he speaks of against this habitat where the bacteria do not proceed to cause suppuration, because no inflammation sets up under these conditions; but they in turn produce the same toxins that are produced by the alveolar abscess, only in this case there is no outlet for this poison. It remains securely locked in this comparatively small space, and the safety of the individual is dependent entirely upon how immune he or she may be against these poisons. Nature provides for the defense of the individual by the cell life that he speaks of, and it is only when these defensive conditions are weakened—it may be by disease, it may be by over-exercise, or it may be through some local cause; but when this defensive power is lessened, then is the time these toxins are taken up by the circulation and carried to some special point, and their manifestation becomes a more or less serious or perhaps a critical one.

The prevention of this condition is the one thing we, as a profession, should give greater consideration to than we have done in the past, because it is the only positive thing we know today that will assure the ultimate preservation of the natural teeth. That means starting with the teeth before the child is born—starting with the education of the mother in regard to the character of the food that makes for proper teeth in the child.

From the time the first teeth are erupted there comes into play the question of focal infection, and that involves the broad question of what may be termed the prophylaxis of the mouth. With this subject we are all familiar, and it is the one great means that dentists must in the future utilize beyond what we are doing at the present time, if we would do our share, as far as our responsibility is concerned, toward the welfare of the teeth of the future race of our country.

In regard to the curative question—and that is the difficult one that confronts us as a profession—the point I would start with is that the dentist is not educated to handle these cases properly when they first present themselves. The dentist has not been instructed in making a proper, careful diagnosis of a mouth where a focal infection is suspected, or where one may exist. Too frequently, when there is just one tooth in question that stands out with a focal infection, the dentist goes right to work at that tooth, and pays very little attention to the rest of the mouth. There may be a dozen other focal infections in the same mouth; that is a point that should be well understood. What does a diagnosis mean? It means, first, that the dentist should have a chart of the mouth that indicates absolutely every tooth in which a devitalized pulp is present, or suspected to be present, and to demonstrate to himself whether such a condition exists; there is nothing of more importance than this.

The next step is to make a diagnosis of the conditions, the symptomatology; whether it is a case in which a pyorrheal condition is combined with a focal condition, or whether perchance there may be a pericemental infection without a devitalized pulp. To make this examination properly is a matter that cannot be done in a few minutes, and frequently not in a few days. It means the proper roentgenographing of the mouth. It means an understanding of the proper physical condition of the individual. A dentist who is handling a case of that kind should have at his command the urinalysis of such a patient, the blood

examination of such a patient, and the opinion of the internist, if there be one in the case. All of those questions become important matters in the decision that he must come to, after he understands properly what the condition of each particular tooth may be. If, for instance, we have a patient in whom the teeth to all intents and purposes, physically, as they express themselves to our view, present the very best of appearances—as I have frequently seen them, where before the use of the X-ray we would never have dreamed of a focal infection—and yet that individual is suffering from marked toxemia, a very marked diabetic condition is present, or a nephritis in a marked degree that has alarmed the internist. That is no case, in my opinion, for prolonged dental treatment—however successfully we may be able to save those teeth, if the condition of the patient were not so serious.

In many of those cases it is important to know what the physical condition is—not as we, as dentists, look at it, but as the physician looks upon it; and it is for that reason that focal conditions of infection should be handled only co-operatively by the physician and the dentist. Often when we know from a careful examination of the roentgenogram of an infected tooth that we have the ability to put that tooth in a healthy condition and to keep it free from infection, we should realize that before that can be properly accomplished we may endanger the life of the patient! Under such circumstances, I do not think there is an individual present who, if he fully realized that fact, would think of attempting to save such a tooth. In other words, the value of the tooth becomes insignificant—much as we dentists may value it—when we compare it with the life of the individual.

Granting that fact, we now come to another stage of the question of the control of focal infection. We have before us, we will assume, an individual in whom the blood examination, urinalysis, and everything else is of such a nature that the internist says, "If you can save those teeth, go ahead and save them."

It is now up to the dentist to determine, "Can I put the tooth, or the teeth, in such condition that these focal points will be not only free from infection, but will remain free from infection?" I contend that it is only partially doing our work if we simply treat those teeth so as to eradicate the infection and not be secure in the belief that they cannot become reinfected. Today I believe that it is almost impossible for any man, after he has completed the eradication of focal infections and put the most valuable kind of work into the operation, and has made a root-filling that meets his satisfaction, to say immediately on the conclusion of the operation that that tooth is safe from infection. I do not believe he can give a safe opinion in regard to a tooth of that kind until from six to twelve months have elapsed. In other words, the only rational proof we have is that there shall be a regenerated alveolar structure where the bone was destroyed, and that it shall remain in that condition. If we fail to secure that result the operation is a failure. Today I do not believe in my own mind that a large number of teeth with devitalized pulps are fit to remain in the human jaw, although fifteen years ago I felt calmly secure in the belief that they could be placed in a healthy condition. I have reduced in my own mind the percentage of such teeth that are fit to remain in the mouth, and while I realize that this is an extremely discordant note to introduce to a body of dentists whose aim is the preservation of the human tooth for the value it has to humanity, yet I can only appeal to you, my brother dentists, in this way: That it is our duty to become big enough in the moral sense to outgrow the natural smallness of all specialists who see only the small field in which they are interested, but constantly to keep before our minds the thought that we, as physicians of the teeth, are just as certainly physicians of the body. We cannot isolate a part from the whole, and when we imperil life we are no credit to ourselves. I do not think there is a man or woman in dentistry who values a human tooth

more than I do, and I realize the wrongs I have done innocently in this respect; and it is for that reason I say we must be careful not to retain in the mouth teeth that are a menace, or are liable to be a menace, to the life of an individual.

The argument is frequently made that as long as the loss of the alveolar structure is not progressive, as long as we can watch such a tooth by means of the roentgenogram, we should keep those teeth, and keep them under observation. Let us stop for a moment and think what it means to keep the teeth of our patients under roentgenographic observation. Is that a practical matter with the majority of our patients, to say the least? You know it is not. Who knows where that patient may be when that immunity to this toxemia may break down? Only three weeks ago I extracted two molars from the mouth of a woman around the age of sixty years, in which I filled the roots about twenty-five years ago. They were teeth filled with nodular pulp matter in such a manner that I failed to reach the foramina of those teeth. I knew it at the time. I spent hours in the treatment of those teeth. I have radiographed those teeth in the past ten years a dozen times, and never found anything but healthy alveolar structure there until about three months ago, when the patient, presenting herself, as she did on regular occasions, for prophylactic treatment, sent word in to me that she thought she would like to have those teeth radiographed again. To my astonishment, I found marked focal infections at the ends of the roots of both those molars. Those teeth were extracted within forty-eight hours. There is a case where the patient of her own accord entirely entered into the question; but how often are we able to find such a condition in this way? I bring up the case as a practical one, to show the fallacy of depending on healthy alveolar structure where we know the root-canal work is intrinsically defective, and what the possibilities in the case of such work may be in the future.

This is no question that can be settled

within the few moments allotted to it for discussion, but I feel that if I leave this point with you, I have accomplished a great deal—namely, there is no such thing as safety in the control of focal infections unless the focal infection is eradicated and the end of the root is hermetically encapsulated, so that it is absolutely free from the possibility of microbic attack in the future.

Dr. D. W. McLean, Mount Vernon, N. Y. That Dr. Mayo's name is one to conjure with in dentistry today, there cannot be any doubt; this assemblage of dentists is sufficient proof. When Dr. Mayo stood before our profession two or three years ago, and, summing up the findings of various research workers on the subject of focal infections, challenged us with the statement that the next great step in preventive medicine must be taken by the dental profession, he assumed a position absolutely unique in this profession. His statement then marked an epoch, and I venture to say that never in the history of any profession has there been such a change of ideals, such a groping for new facts and knowledge, such a revolution in technique, as has taken place in our profession in that short time. Up to that time it was considered by most of us a safe and proper procedure to half-devitalize pulps and half-fill root-canals with cotton medicated with iodoform, or with mummifying paste, or almost anything else that was small enough to go into a root-canal. We had no radiographs. We never knew if we reached the end of the root, or how near to it we were. Today, in looking at radiographs of those teeth we must keep that fact in mind. It is not well to knock the work of a few years ago, or to slur the work of the men who did it. Sometimes today we must make four or five attempts to fill a root-canal, and radiograph the canal after each attempt. What hope could there be to fill these root-canals without the help of the radiograph?

Dr. Mayo and Dr. Rhein have covered the general features of the subject so thoroughly that there is very little more to say about it. We all approach these

subjects from different angles, otherwise the discussion would be nothing but a chorus; and I approach the subject from the angle, as most of you do, of the very busy and very tired general practitioner. The question is, What does this subject mean to you and to me practically, in our everyday work, as general practitioners? You hear men say that, for all the talk of focal infections, they see very little of them and they doubt if there is as much fire as the tremendous amount of smoke would indicate. I can only quote what Dr. Weston A. Price is fond of quoting: "A new truth is a new sense." If we study and look for these cases we will develop a sense of sight that will discover them on every hand.

A patient comes into our office, and we remove a tooth. The patient tells us when we see him again that he was laid up with a severe cold, or an attack of grip or rheumatism, following the extraction. What does that mean? It means a focus of infection. It means we have stirred up a hornet's nest in the alveolar tissue surrounding that tooth, that there has been a fresh invasion of the patient's system, and the reserves were called out; and while the reserves and the germs were fighting it out, the patient went to bed; he was sick.

There lies our tremendous responsibility. We are fond of criticizing the medical profession for the tendency some of its members have to go over our heads and condemn teeth. About a week ago a patient came into my office and said she wished a root extracted, because she was suffering from rheumatism. The physician had examined the mouth, and the root was the only thing he found there to cause the trouble. There was a great deal of pyorrhea, but the patient was quite indignant when I spoke of it, and said the physician had examined the mouth and said there was no pyorrhea! We all have had cases where the physician has sent the patient to the radiologist and has made his dental diagnosis as well as medical, and we recall the fact that that is practicing dentistry, and even a physician cannot practice dentistry without vio-

lating the law of the state. But he is often justified. Suppose you were a physician treating a case of focal infection with secondary lesions. Suppose you had eliminated almost everything else, and you felt sure the trouble was in the mouth and the teeth, and you sent your patient to a dentist who for the past ten years had been suffering from mental ankylosis. What would you do? You would be justified in taking that patient away from that dentist and putting him in more competent hands. Very often, however, the same condition exists the other way around.

I have been treating and I hope to show you the radiographs of a patient with acute arthritis. We have eliminated every focus of infection in the mouth with the exception of one suspicious vital pulp. So far we have found nothing. That patient ought to be in the hands of a competent group of men working together. I have referred her to her physician—I did so early in the treatment of the case—and he said her rheumatism "came from the air." What should the dentist do in a case like that? The subject of focal infections lies out in No-man's Land between the two professions, and *neither one alone* can treat it thoroughly and to its full completion.

I was impressed with Dr. Rhein's statement as to the prevention of focal infection; and the body of men in this State Society today that is doing the biggest work toward saving people from these focal infections is your Oral Hygiene Committee. It boils down to a question of prevention; of examining the teeth frequently. We must spend our time filling pinhole cavities, instead of treating pulps—or capping them, which I believe to be equally bad.

When it comes to preventing focal infections, there are a lot of questions of technique that cannot be entered upon here. As to selection of the root-canal filling material—it takes courage to say it, but personally I do not believe chloropercha is the agent that is going to do it, though this is a question that time must prove. Chloropercha is absorbent, and it is neutral. A much better material

to my mind is the bismuth-iodoform-formocresol paste. We seldom fill a canal when every bit of infection beyond the apex has been destroyed. The surgeon can destroy that infection absolutely with the knife, but when he cannot remove it I note that he is not very prone to inject a foreign body, especially a neutral absorbent foreign body like gutta-percha, and seal the case up.

What teeth shall we remove, and what teeth shall we save? Dr. Rhein has certainly covered that question thoroughly. We must study the case. If there is a secondary complication which is serious, most certainly those teeth should not be left there. On the other hand, there has been a widespread extraction of teeth in the last two or three years that has been absolutely uncalled for, and when the pendulum has swung back between the two extremes and has come to rest I believe we shall extract infected teeth only in cases that show secondary lesions.

When root-canals are ready to fill, we should "culture" them in all suspicious cases. The culturing of a tooth is a simple matter. The local bacteriologist will supply you with tubes of broth or nutrient agar for that purpose. The tooth is isolated, washed with alcohol and dried, and a sterile instrument is passed through the apex and then gently drawn across the agar; the cap is put on the tube, which is then sent to the bacteriologist.

When we think the canal and the tissues beyond are sterile, we place a small wisp of cotton in the canal, and leave it for two or three weeks; then carefully remove it and clip off from the apical end an eighth of an inch, drop it into broth, and send that for culture. If the report comes back that some form of streptococcus, viridans or hemolyzing, or even staphylococcus, is present, the sterilization of the apical tissues has failed, and the tooth should be removed.

We must remember that a tooth may be infected and show no lesion in the radiograph. Men frequently speak of seeing infection in a radiograph; it can't be done. We may see things *from which we deduce infection* but the only thing

which *will actually show infection is the microscope.*

One other important point is to be sure not to forget the vital pulps. Last October at the National meeting, Dr. Rose now reported cases where the infection was found in capped pulps. Infection taken from a putrescent pulp was injected into rabbits, and in 50 per cent. produced pulpitis in perfectly sound teeth. We know that the bacteria mixed up in the process of caries penetrate beyond the actual zone of decay and may reach the pulp. Or again, circulatory changes may take place there, the resistance may be lowered, and that pulp may become the seat of an infection which is hematogenous in its origin. Or, in the case of the capped pulp, the infection may enter the pulp direct—and I believe a great many of these pulps are infected before they are sealed.

I have been very much interested in the subject of encapsulation, as we all have. Unless a root-end can be hermetically sealed the space between the root-end and the gutta-percha becomes a lodging-place for bacteria, and the encapsulation is a source of danger rather than a protection. And I believe the chloro-percha will not adhere, for the reason that the root-end is invariably moist.

The statement has been made that the chloroform in the mixture will dry the end of the root, and the mass will adhere. I have felt very sure this was not the case, but for some time was at a loss to prove it. I finally set up some extracted single-rooted teeth in fresh meat (which is moist) and buried them, to the crowns, in plaster of Paris. The roots were then encapsulated, some with chloro-percha and gutta-percha points, and some with Callahan's rosin solution followed by chloro-percha and points. They were then radiographed, and laid aside for twenty-four hours, after which the plaster of Paris and meat were removed. It was found that not one of the chloro-percha encapsulations had adhered to the root, though all had adhered tenaciously to the meat. The encapsulations containing the rosin solution showed a

tendency to adhere, but in every case there was a considerable fringe of material which did not adhere in the slightest. The teeth were dropped in ink for twenty-four hours, and the ink proved the facts by penetrating under the encapsulation.

Dr. WESTON A. PRICE, Cleveland, Ohio, then gave an illustrated lecture, entitled "A Study of the Conditions which Indicate Whether or Not a Tooth Should be Extracted."

[This lecture is not published here for the reason that no revised manuscript was received from the author.—Ed.]

Adjournment.

FRIDAY—*Morning Session.*

The society was called to order by the president, Dr. A. C. Rich, at 11 o'clock, in the Convention hall. Dr. WM. DWIGHT TRACY of New York read a paper entitled "The Next Quarter-Century in Dentistry: A Prophecy Based on the Needs of the Profession and on Our Hopes for Its Development."

[This paper will be published in our next issue.—Ed.]

Adjourned until the afternoon session.

FRIDAY—*Afternoon Session.*

President Rich called the meeting to order at 5 o'clock, and Dr. A. W. TWIGGAR of Ossining, N. Y., read the Report of the Executive Council.

On motion, the report of the Council was approved.

The next order of business was the installation of officers.

Dr. G. B. Beach, of Syracuse, the newly elected president, was conducted to the platform.

Dr. AMOS RICH. *Dr. Beach*,—After your many years of faithful and arduous service, this body has seen fit to select you for this important office. I congratulate this society upon its selection, and it is with considerable pleasure that

I hand this gavel over to you, and wish you all success in the discharge of your duties.

Dr. G. B. BEACH. In assuming the office of president of this society, I take it with mixed feelings. It is an honor which has come upon me so suddenly as to hardly permit me to express myself intelligently. I can only wish for the co-operation of every district, and of every man in every district. We have troublous times about us, but there is no reason why our dental affairs should suffer materially. More work brings us closer together, and makes us more dependent one upon the other.

In this beautiful hall perhaps it is a fitting time to express our appreciation of what our retiring president has done for us in providing this beautiful place of meeting and these beautiful patriotic decorations, which are a great inspiration to us.

I ask you to aid me in this great work which is before me, and I feel you will.

I thank you, Mr. President and gentlemen, for this honor, which I very deeply appreciate.

Dr. A. L. SWIFT, New York. I would move a vote of appreciation to the City of Saratoga Springs, and to our retiring president, for all the courtesies which have been extended to us, and for permitting us to meet in this beautiful hall amid these beautiful decorations.

The motion was carried.

Adjournment.

BANQUET.

An informal banquet was held on Friday evening, at the Masonic Temple, which was largely attended by the members and guests. Dr. Amos C. Rich acted as toastmaster.

Dr. RICH. We come now to the part of the program which is one of the most pleasing duties the president has to perform. I refer to the awarding of the William Jarvis Fellowship Medal. It is my pleasure this year to be able to pre-

sent it to Dr. George H. Wilson of Cleveland, Ohio, who will thus be made a Fellow of the Dental Society of the State of New York.

Dr. Wilson,—Through the generosity of Dr. William Jarvie, actuated by his interest in this society, a Fellowship Fund was created, and each year some dentist of the United States or Canada who is considered worthy of the honor is made a Fellow of the Dental Society of the State of New York, because of his distinguished service to the profession of which he is a member. You have been selected this year to become such a Fellow. Your record speaks for itself: it is known by the profession. It is therefore unnecessary for me to refer to it—it was sufficient for the committee to select you as its choice. It becomes my duty, in my official capacity, to pronounce you a Fellow of the Dental Society of the State of New York, in token of which I hereby confer upon you this decoration, which designates you as such. It is my privilege, in my personal capacity and on behalf of the society, to congratulate you upon your preferment.

Dr. GEORGE H. WILSON, Cleveland, Ohio. Mr. Toastmaster, ladies and gentlemen,—I hardly know what to say at this time, because it is an honor I never expected would come to me; and when your president wrote me and informed me that I had been so selected, it was a question in my mind whether he could possibly be right, or whether there was not some error.

Friends, I feel this recognition is the greatest honor that can be conferred upon any member of the profession, because it is a recognition of what he has done. It is not asking him to do something in the future. It is a distinction. It is a joy, and it is a sorrow—because it is placing one on a pedestal, as it were, and he cannot help but feel a responsibility to his profession. He feels he must be a model, that he is one to whom the younger men will look up, and they will size up the profession by their models; so it is a great responsibility placed upon one. I have prided myself that I was independent in action and

speech, that I was neither a model nor a devotee to some other mentality; but now, as a model, I am under greater obligation to consider the effect, upon the rising generation, of my actions and speech. I have had a good deal of faith in the Greek philosophy of Hedonism, that what we do, we do because of the pleasure it gives us. I believe that such a motive is worthy, provided we have a proper control. If we are blessed with a mother who had great faith in the word of the Teacher of Galilee, and most of us have been, that it is more blessed to give than to receive, then Hedonism is a worthy mainspring of action, because it gives us pleasure to do for others.

There are two reasons why I am especially glad that this honor came to me at this time—one for my own sake, and the other for the department of dentistry which I represent, if I represent anything at all. I have felt that the prosthetic department of dentistry was not looked upon by the mass of the profession as it should be. That was one of the reasons I never aspired to this honor, because I thought it was impossible for the profession at this time to properly estimate prosthesis; therefore I am especially pleased that it comes to me as a representative of prosthetics. At the present time, I cannot help but feel that the prosthetic department is assuming a new dignity. We have had it intimated tonight how that was brought about—by the famous article of Hunter, when he spoke of “American septic dentistry.” It hurt us, it jarred us, but it did us good. For that reason we cannot but think, if we think logically, that the prosthetic department must be one of the greatest departments of the future for this generation; at least I hope our operative department will so teach that there will not be that need for prosthetic dentistry in the future. Preventive dentistry is the subject that should be taught and practiced as far as possible by the operators, but it is not possible for them to remedy the harm we have done in the past, therefore we must have our prosthodontists. I am constrained to say the probabilities are that at our next Na-

tional meeting an organization will be formed of the prosthetists of our profession, and we hope it will mark a new era in the progress of dentistry.

I said I felt this was the greatest honor that can come to any man in the dental profession. I will say it is the greatest honor a dentist can have in his life, save one, and that is the honor of worthy children. I believe every mother and father present will agree with me that the greatest honor in this life is our children, and especially if a kind Providence grants to us such children that they are an improvement upon the parent, that they are better physically and mentally. Then again, if our sons seek to follow our own profession we can feel that our life is not in vain, and our name, if we have made one, does not cease with our death, but goes on for another generation at least.

I feel this medal, and what it represents, is the greatest honor a profession can give to its members. I am glad Dr. Jarvie found it in his heart to create this foundation, because it is said that the dental profession is very ungrateful. They will take everything and give nothing. This medal gives the lie to that statement. It shows to us that the profession does acknowledge and is thoughtful of those who are working along in a quiet, unpretentious way, and it is giving us the bouquet before our death.

I thank you, one and all, for the honor you have bestowed upon me.

DR. RICH. It is my privilege to make a special presentation to one who has unselfishly given his time and his money for the benefit of dentistry in the State of New York. Ladies and gentlemen, I refer to Dr. William Carr, of New York. By resolution of the Council, engrossed resolutions commemorative of his services have been prepared, and it is my privilege to present them to him this evening. Dr. Carr, it gives me exceeding pleasure to be the person to present these resolutions of appreciation to you.

DR. WILLIAM CARR. New York. *Mr. President, ladies and gentlemen, members of the New York State Dental*

Society,—This is one of the proudest moments of my life, for which I thank you sincerely, as I believe that these resolutions express your appreciation of my activities as chairman of the Law Committee for the enforcement of the dental law. Thirty-three of the best years of my life have been given unselfishly to the enforcement of this law, in the endeavor to raise our professional standard. I have been severely criticized by friends of illegal practitioners whom I have prosecuted, and criticized by legally qualified practitioners who employed in their offices men practicing illegally. Under existing laws it is much easier than heretofore to prosecute offenders successfully. The state will never be entirely rid of them, as they are like the Lord's poor—always with us. I earnestly beseech you to give hearty support to those having charge of the enforcement of the dental law, giving them whatever aid is within your power.

Again I thank you sincerely for this expression of your appreciation.

In addition to the presentation of the Fellowship medal to Dr. Wilson and the resolutions of appreciation to Dr. Carr, the audience listened to after-dinner speeches from Dr. Donald M. Gallie, Chicago, Ill.; Dr. A. P. Burkhardt, Auburn; Dr. Frank B. Darby, Elmira; Mrs. H. W. Gillett, New York; Dr. Augustus S. Downing, Asst. Commissioner of Education, Albany, and Dr. H. J. Burkhardt, Rochester.

DR. RICH. Permit me from the bottom of my heart to thank you all for your cordial support and your continued presence here this evening until this late hour. My guests and speakers, past presidents, and charter members, permit me to extend my thanks.

DR. BURKHART. I want to move a resolution of thanks to Dr. Gallie for coming here, and for the greetings he has brought to us from the Illinois State Society.

The motion was carried unanimously.

Adjourned.

New Jersey State Dental Society.

Forty-eighth Annual Convention, held in Atlantic City, N. J.,
July 17 to 19, 1918.

WEDNESDAY—*Morning Session.*

THE forty-eighth annual convention of the New Jersey State Dental Society was held at Young's Million Dollar Pier, Atlantic City, N. J., July 17, 18, and 19, 1918.

President Raymonde A. Albray, Newark, N. J., called the convention to order at 10.30 o'clock.

The Rev. ROBERT ARTHUR ELWOOD, Atlantic City, opened the meeting with prayer.

The PRESIDENT. I will ask Dr. Elwood to deliver the address of welcome.

[Dr. Elwood's welcoming and patriotic address was enthusiastically received.]

The PRESIDENT. We will now listen to a patriotic address on "The Fight for Democracy" by Mr. Chas. Richard Williams of the National Security League.

[Mr. Williams gave a timely and interesting address contrasting Hun with American ideals, which was highly appreciated by his audience.]

The PRESIDENT. The first order of business is the roll-call.

On motion by Dr. WOOLVERTON, duly seconded, the roll-call was dispensed with.

The PRESIDENT. Next in order is the reading of the minutes of the last meeting.

On motion of Dr. WOOLVERTON, duly seconded, the reading of the minutes was dispensed with.

Dr. WOOLVERTON. Mr. President, I move that the minutes as printed by

the DENTAL COSMOS, which have been distributed to each member of this society, stand approved as printed unless there are some corrections to be made.

The motion was seconded and carried.

The PRESIDENT. The next order of business is the annual Address of the President.

Vice-president George W. Wakeley was called to the chair, and President Albray read the annual Address of the President, as follows:

President's Address.

By RAYMONDE ADAIR ALBRAY, D.D.S.,
Newark, N. J.

Mr. Vice-president, fellow members and guests.—The meeting which opens today is the culmination of a great deal of thought and work on the part of many of our members, and it gives me great pleasure to bid you all welcome.

An excellent program has been provided for you by the various committees. Dr. Egel, chairman of the Essay Committee, has secured men of national reputation to address you; Dr. Stillwell of the Clinic Committee has striven to obtain clinicians who are worth while, and I am sure you will agree with me that he has succeeded admirably. Make it a point to attend both the lectures and the clinics, that you may acquire knowledge, that your patients may be better served, and that our essayists and clinicians shall be accorded the honor which is due to men who sacrifice their private interests for the enlightenment of the profession and the good of the people.

Dr. Callahan, chairman of the Exhibit Committee, has, in the face of uncertain traffic conditions, decreased production, and labor shortage, procured a remarkably large and interesting manufacturers' exhibit which will prove an inspiration to our members.

The work of the various committees throughout the year has been well done, and to the chairmen and members of all committees, to Dr. Halsey our treasurer, to Dr. Gelston, who has devoted a great deal of time and energy to the proper staging of this convention, and to Dr. Forsyth, our secretary who so successfully carries on the greater part of the society's work, I say "Thank you" for the hearty support and co-operation which you have given your presiding officer.

The past year has been a trying one for all. A spirit of unrest and uncertainty has pervaded our daily lives. We have seen our relatives and friends depart for camp and the front. Many of our fellow practitioners have given up practice to enter Government service. Those of us who are here do not know what the future may hold. The period of reconstruction after the war will undoubtedly be a trying one. Some of our members may require help, our country may need far more than we have been called upon to give. Therefore it behooves us to maintain our organization and strengthen it in every way possible, that it be in a position to exert its greatest power at the time when it will do the most good.

I ask that petty jealousies and differences which have crept into one or two of our local societies be forgotten, and matters so adjusted that harmony and good feeling will prevail throughout our entire organization. We all wish for the advancement of dentistry, and it is largely through our societies that this is accomplished. Discord, even to a slight degree, seriously hampers the working of an organization and detracts largely from its efficiency and power. There is sufficient of combat "over there" to suit any one. Let us have peace.

PAYMENT OF DUES.

A matter that I wish to bring before you, which has been the cause of quite a little confusion, has necessitated several extra meetings of the Board of Trustees and has caused Dr. Forsyth a tremendous amount of extra work, is the carelessness of local society secretaries in collecting dues and making remittances. Because of this remissness on the part of several secretaries, quite a number of our members were suspended from the National Dental Association and lost several copies of the *National Dental Journal*. Promptness in collecting dues and promptness in making remittances of State and National Society dues to our secretary will greatly facilitate and lighten his work, will insure membership in the State and National societies, and will strengthen the local society. A member who has paid his dues is always a better member than one who has not done so, and a society made up of men who consider dues an obligation to be met promptly is bound to be a success. See that yours is this kind of a society!

Recommendation No. 1. In this connection I wish to make a recommendation to the effect that any member of a local society, or a member of the New Jersey State Dental Society who is not a member of a local society, whose dues are not paid by March 1st of any year be suspended from all privileges of the local, State, or National societies until January 1st of the following year, and unless the arrearage in dues and the next year's dues are paid by that date, he be automatically dropped from membership.

MEMBERSHIP.

Recommendation No. 2. The members of our societies should be selected with some degree of care and with an eye to their qualifications in maintaining the standard of the society. For the protection of the membership of the local, State, and National organizations, I recommend that a ruling be made that the names of all applicants for member-

ship in local societies be referred to the secretary of the State Society before a candidate can be elected, that the record of the applicant can be investigated and transmitted to the local society.

The secretary of the State Society, of course, would not be invested with power to say that a man could or could not be accepted, but simply empowered to send the local society any data in his records as a guide in determining the desirability of the applicant.

It has not been possible to secure the names of all of our members who are in Government service, so in making up the program it was deemed best not to print any names, but simply dedicate a page to those who have entered the army or navy. We are proud of the number who have responded from New Jersey, and especially gratified to know that many of them have been advanced in rank. I ask that every man in this room send a note from Atlantic City to at least one of our members who are in active service, to let the boys know that we are thinking of them.

One matter of considerable importance in which our society had a part was the recognition by the Government of the advisability of having dentists serve with the local exemption boards. This was taken up at a meeting of the Board of Trustees, and brought to the attention of the Adjutant-general of the State. He in turn communicated with the authorities in Washington, and shortly afterward orders were promulgated which made possible the appointment of dentists to these boards.

Unfortunately the impression has gotten abroad that New Jersey dentists are not doing their full share of work in making men dentally fit for the army or navy. I regret this exceedingly, because it is not only untrue but unjust. The dentists of our state are fully as patriotic as those of any other state, and I know that a great deal of dental work has been done and is being done for soldiers, sailors, and recruits, and also in various parts of the state for the families of soldiers and sailors in connection with

the Home Service section of the Red Cross. That our men have not considered it necessary to run to a mail-box and send a postal card every time a filling was put in the tooth of a soldier should not be taken as an indication of uninterestedness, disinterestedness, or lack of patriotism. Quite the contrary.

New Jersey dentists were early in the field and organized for the purpose of rendering free dental service to the men entering the army or navy, and they are going to keep right on doing their bit in this as well as in other ways. In Newark, since January, over three hundred members of soldiers' or sailors' families have been cared for by dentists of the district, working through the Home Service section of the Red Cross.

EXEMPTION FROM JURY DUTY.

Recommendation No. 3. Our old friend "exemption from jury duty" is before us once more, and with the proper support from our members probably could be made effective, and I recommend that the incoming Legislative Committee make a strenuous effort to secure the passage of such legislation.

AMENDMENT TO THE DENTAL LAW.

Recommendation No. 4. The New York dental law contains a clause which has been upheld by the Supreme Court of that state. The clause in question is, in effect, that "It is illegal to practice dentistry under a false or assumed name, or under the license or registration of another person of the same name, or under the name of a corporation, association, parlor, or trade name." And I recommend that the Legislative Committee be instructed to have such an amendment to our present dental law framed, and endeavor to secure its enactment.

During the past year the State Board of Registration and Examination in Dentistry has been very successful in the prosecution and conviction of illegal practitioners in the state. The Attorney-general of the State has been most gener-

ous in the time devoted to the prosecution of cases.

Recommendation No. 5. I think it would be a timely and courteous action on the part of this society to extend a vote of appreciation to the board, and to the Attorney-general, and so recommend.

Recommendation No. 6. Each year after the convention closes there is a vast amount of business which has to be finished up, the details of which are familiar only to the officers of the society who had the arrangements in charge. The question of just when the newly elected officers assume charge of the affairs of the society has never arisen, and I recommend that the society specify that the terms of officers begin on the 1st day of September following their election. This will allow sufficient time for those who have arranged and conducted each annual meeting to complete all business and turn over the affairs of the society to the incoming officers in proper shape.

NEW JERSEY DENTAL JOURNAL.

Recommendation No. 7. The *New Jersey Dental Journal* is now in its seventh year. It has from a number of standpoints been a success. Articles published in its pages have been reprinted in other journals, at home and abroad. In various ways it has saved this society money in considerable sums; printing the convention program has effected a saving of nearly five hundred dollars per year to the society. Other state societies have inaugurated journals or bulletins patterned after ours. The members of the Publication Committee have labored hard to give the society an interesting and useful monthly magazine, containing original articles, valuable reprints from other publications, and news of the local societies in the state. In most instances our support has been meager, and repeated attempts to arouse enthusiasm for the *Journal* have met apathetic response or none at all, and I therefore recommend that the society discontinue the publication of the *New Jersey Dental Journal*.

ELECTION OF OFFICERS.

You have all had a copy of the proposed changes in the by-laws, and I wish at this time to urge you to adopt those sections which have to do with the election of the officers of this society and the members to be recommended to the Governor for appointment to the State Board of Registration and Examination in Dentistry. The practical effect of adopting this system of elections is as follows: (1) Tiresome nominating speeches will be a thing of the past. (2) A great deal of valuable time will be saved, thus making it possible to utilize a whole morning session for other matters.

The proposed scheme is simply that which is in vogue in most of our municipalities. There are many other features to commend the plan, but I do not think it necessary to enumerate them here, as I know you all have sufficient intelligence to see them. I consider that this plan of electing officers will be for the best interests of the society, and again urge you to vote for its adoption.

Recommendation No. 8. Several parts of our present by-laws are rather vague or involved and could be misinterpreted. To correct this condition I recommend that a committee be appointed to make the wording of these portions more explicit.

I wish to extend the thanks of the officers of the society to essayists, clinicians, exhibitors, and members who have aided in making this meeting possible, and I hope that each and every one will go away feeling well repaid for having attended the forty-eighth annual convention of the New Jersey State Dental Society.

Chairman WAKELEY. I will appoint as the Committee on the President's Address, Dr. Van Gieson, Dr. Barry, Dr. Gleason, Dr. Faupel, and Dr. Woolverton.

There being no proposals for membership and no appointment of special committees, the President next called for the report of the Committee on Necrology.

REPORT OF COMMITTEE ON NECROLOGY.

Dr. GEORGE M. HOLDEN, chairman, reported as follows:

Since our last meeting four members of the New Jersey State Dental Society have passed away. As an expression of respect to their memory, we request that the members rise while the names are being read.

Dr. RICHARD F. BORDEN, Bound Brook, N. J., formerly of Red Bank, N. J. Began practice about 1865; joined this society in 1907. Died in 1918.

Dr. JACOB P. MILLER, Bayonne, N. J. Graduated from the New York College of Dentistry in 1913; joined this society in 1914. Died in January 1918.

Dr. P. J. WILSON, Newark, N. J. Began practice in 1866; joined this society in 1897. Died January 1, 1918.

Dr. HENRY B. JOHNSTON, Dover, N. J. Graduated from the Baltimore College of Dental Surgery in 1902; joined this society in 1912. Died March 31, 1918.

RESOLUTIONS OF REGRET.

Whereas, by an act of Providence we have suffered the loss of our fellow member, Dr. Richard F. Borden; be it

RESOLVED, That we, the members of the New Jersey State Dental Society, hereby express our sorrow and sympathy, and record our appreciation of his faithful services; and be it further

RESOLVED, That these resolutions be placed upon the minutes of this society, and that a copy be sent to the family.

GEO. M. HOLDEN, *Chairman*,
CHAUNCEY M. F. EGEL,
CLARENCE O. S. HOWE,
CHAS. A. RICE,

Committee.

Similar resolutions are presented for adoption in the cases of Dr. J. P. Miller, Dr. P. J. Wilson, and Dr. H. B. Johnston.

Motion was made and carried that the report of the Committee on Necrology be received and ordered placed upon the minutes, with instructions to carry out the recommendations.

Sundry reports were called for by the President, and such as were ready, in-

cluding those of the Secretary and Treasurer, were accepted and ordered embodied in the minutes.

The PRESIDENT. Next is the report of the delegate to the National Dental Association, Dr. Fowler.

Dr. HENRY FOWLER. *Mr. President, and gentlemen of the Convention*,—Your delegate to the National Convention attended, and as most of the members have no doubt read in detail the report of the activities of that convention, it was not deemed necessary to submit to you a lengthy report. I wish, however, to report that the New Jersey State Dental Society is now in better standing with the National organization than at any time heretofore. The membership of our society is very high in proportion to the total number of practitioners, as compared with the other states, and we feel that the progress which has been made by our society is very good indeed.

The PRESIDENT. The next order of business is the report of the Publication Committee. I have not prepared a separate report of the Publication Committee, as I think the report in my presidential address is sufficient.

PREPAREDNESS LEAGUE COMMITTEE.

We will now hear the report from the Committee on Preparedness League, Dr. J. B. Stevens, chairman.

Dr. J. B. STEVENS. *Mr. President and gentlemen*,—The Preparedness League work in the State of New Jersey began some time before the declaration of war by President Wilson. The committee was organized largely through the efforts of Dr. S. M. Hinman of Cranford, N. J. We began a campaign of dental preparedness which finally culminated in a meeting of the representative men from all over the state, at the Battin high school, in Elizabeth, N. J.

Dr. Egel of Westfield was appointed chairman, and as many of you know, we started out with high hopes and bright prospects indeed. After considerable discussion, upon motion by Dr. Hinman,

our further activities were turned over to the Board of Trustees. At the next meeting of the board, on account of the sudden illness of Dr. Hinman, I was appointed chairman of the Preparedness Committee. Dr. Hinman had collected a small sum for the purposes of the organization. Total receipts as reported to me, by our treasurer Dr. J. B. Goodall, was \$346.00, the expenditures being \$344.05, leaving a balance of \$1.95. Our secretary, Dr. J. C. Forsyth, has the data. Dr. Goodall is in the service, and has requested me to make the report for him.

On account of the complicated procedure required, our men have not made a detailed report of the work done for recruits. Heretofore they did not think it necessary. However, we now have a system (a franked card, form 3-D), devised by Dr. Ash, that will facilitate the matter, and hereafter our work for the registrants will be recorded as it is in other states, and we will make a better showing, on paper.

Camp Dix is prepared to do all kinds of dental work. Dr. Albray and I went down a few weeks ago, and we found a wonderful establishment—all that could possibly be desired. The men are furnished with all the modern facilities of a dental office, even to the wonderful S. S. White nitrous oxid and oxygen machine.

On motion the convention adjourned until the evening session at 8 o'clock.

WEDNESDAY—*Evening Session.*

President Albray called the meeting to order at 8.30 o'clock.

THE PRESIDENT. I take pleasure in introducing to you Dr. Charles F. Ash, New York City, Director-general for the United States, Preparedness League of American Dentists.

DR. CHARLES F. ASH. *Mr. Chairman and gentlemen,*—From New Jersey we have received records of 234 operations. It is almost unfair to New Jersey to print the records of the operations, for the reason that I am satisfied you have

done many thousand operations, and you should have the full credit for it. The people in the other states do not know that you are doing the work as I do. When we read the record, or the report, and see 234 operations as all that is credited to New Jersey—just a couple of hundred operations, whereas the other states have been doing some thousands—it is not the kind of showing that should be made in justice to the men who are doing the work.

There have been several different types of form cards that have been sent out. Here is a card that we had used for this purpose [card produced]. I have endeavored to simplify the cards so as to make them more simple, and make a minimum amount of work in recording the operation, and this card which you will receive now is the one Dr. Stevens has asked me to send to you through the local directors of the League. There is no return portion on it. Either these will be handed out to the registrant, and he will be referred to the dentist who will do the work, or else he will receive this notification card through the mail. The applicant then is given a dental examination. After the card gets into the hands of the registrant he takes it to the man who is going to do the work for him, and the dentist will be instructed how to use these cards. This circular [exhibiting] contains instructions to dentists, and you are requested to read it very carefully. This card is well adapted for a record for a Government report. Turn it over and draw a single line through the address of the registrant, and then mail at once; no stamp is needed. In this lower corner, on the other side of the card, you will observe it says, "Notice to Postmaster: When the address on this card has been cancelled, please deliver to 50 East 42d st., New York City." It is a simple matter to record your operations here. You can sign the card, scratch out the address, and drop it in the mail-box, and by so doing we will be able to have these records for the Surgeon-general's Office, and we will be able to give to the New

Jersey Dental Society the credit which it so justly deserves.

The PRESIDENT. I trust that every man in the room understands the proposition, and that you will all follow the speaker's instructions, for the good of the profession and for the good of the men making up our fighting forces.

We have with us tonight Mr. SAMUEL G. SUPPLEE of New York, who will favor us with a lecture on the subject of "Classification of Tissue Conditions for Convenience in Discussing Prosthetic Problems."

[This paper is printed in full at page 996 of this issue of the DENTAL COSMOS.]

The President next introduced Dr. THOMAS G. ALLER of Philadelphia, who addressed the society on the subject of "War Surgery," as follows:

War Surgery.

Dr. THOMAS G. ALLER, Philadelphia, Pa.

Mr. President and gentlemen,—I am sure that the well-known saying of General Sherman has been very forcibly brought home to us all during the present war. However, as we know, from evil sometimes comes good, and through all this war we ought to be as optimistic as we possibly can, and see the several things that have been given to us, particularly in the arts and the sciences, and especially in dentistry and surgery.

Looking back over the history of surgery, there are really three great periods: First, the period from its incipency up to the time of Ambroise Paré and Larry, who were surgeons of Napoleon's army. Up to that time it was very academic; there was very little in the way of surgery, or anything called by that name, that was of service in the army. They were the originators of the system, in a way, that we have today. If some of the cases we have pictures of tonight had been found on the battle-field at that time, undoubtedly they would have been condemned to death. At that time if a man was mutilated about the face and

jaws to such an extent that it looked as if he could never recover, they deliberately put the man to death. At the present time, however, a very large percentage of such cases are saved; when a man is found on the battle-field showing any signs of life, of course he is taken care of and every facility is afforded him to be restored.

After the time of Ambroise Paré there was no particular advance until Lister, who brought out antiseptic surgery and thus was developed the aseptic surgery of the present.

From that time up to the beginning of the present war no further great step had been taken—or no great advance made. Certain instruments had been devised and operations planned and carried out, but nothing of such decided importance as the things that are now being brought out, namely, the speedier handling of wounded and the shortening of the time of the healing of a wound. Reports come from different parts of Europe showing the wonderful progress that has been made, and giving statistics. The question arose as to just what was the cause of some men's getting good results in various areas by certain methods? Was it the technique, or the medicaments they used? It was found that there was one factor common to all the men that got the good results—they were men who saw all their cases early.

If a case is seen within three hours after being wounded, or at the outside not beyond eight hours, there is a very much better chance for early recovery, or recovery without infection, because by that time the germs are still superficial. True it is that the tissue is frequently very severely lacerated and contused, and if given time it will undoubtedly slough away. The fact of getting cases early allows the surgeon to cut away that tissue, or the part that is so badly bruised, and cut away at the same time the superficial infection.

I now want to show you some slides and bring out several points—one of great importance, namely, the importance that dentistry and oral surgery has attained in this war; also to show

you the difference between the older and newer methods—that is, allowing wounds to heal by cicatrization, or immediate surgical interference. The new idea of seeing cases as early as possible is of greatest importance. Therefore the Surgeon-general has formed units composed of a head surgeon, eye surgeon, nose-and-throat surgeon, an oral surgeon, and two dental surgeons. That constitutes what is called a “head” unit; these head units are sent out to the hospitals where they will be able to see and treat the cases within a few hours, preferably three hours, after they are wounded, and in that way save very materially the length of time the men must remain in the hospital. [At this point Dr. Aller threw pictures on the screen.]

On motion, duly seconded, a vote of thanks was tendered to Dr. Supplee and Dr. Aller for the interesting papers read to the convention.

On motion, the convention adjourned until the Thursday morning session at 9 o'clock.

THURSDAY—Morning Session.

President Albray called the meeting to order at 10 o'clock.

The PRESIDENT. The next order of business is the election of officers.

Dr. HOPKINS. Before we proceed with the election, Mr. President, I rise as a special privilege. I would like to present a resolution. The members here see a beautiful service flag on the wall behind the president's chair, which was made and presented to us by the wife of one of our members. I move a rising vote of thanks to that lady, Mrs. Wm. H. Gelston of Camden, for making and presenting to the society that beautiful service flag; also that the secretary be instructed to present this resolution to her.

The motion was seconded and unanimously carried.

ELECTION OF OFFICERS.

The next business in order was the election of officers for the ensuing year, which resulted as follows:

President—Dr. George W. Wakeley.

Vice-president—Dr. Charles F. Jones.

Secretary—Dr. John C. Forsyth.

Treasurer—Dr. Joseph G. Halsey.

Delegate to National Dental Association—Dr. Wm. E. Truex. Alternate, Dr. E. Stillwell.

Nominations for Examining Board—Dr. Chas. A. Spahn, Dr. Thos. J. McLernon, Dr. Eugene Griggs, Dr. Wm. I. Thompson, Dr. Wm. H. Gelston, Dr. Geo. H. Grim.

Dr. BARRY. I move that the names of the six men selected by the society be sent to the Governor, and be recommended to the Governor, from which he shall select two men for the places of the retiring members of the State Board, and that no comment shall be made with respect to any of the men. (Motion carried.)

Board of Trustees.

The following names were submitted by the component societies:

Atlantic: Dr. M. P. Shoemaker.

Bergen: Dr. Walter A. Tracy.

Central: Dr. Edward C. Stillwell.

Clinical: Dr. R. B. Van Gieson.

Hudson: Dr. Chas. Faupel.

Mercer: Dr. Geo. W. Wilkens.

Middlesex: Dr. W. W. Hodges.

Monmouth: Dr. Frank L. Manning.

Passaic: Dr. Chas. A. Rice.

Plainfield: Dr. Frank T. Clawson.

Southern: Dr. Wm. H. Gelston.

Tri-County: Dr. L. R. Fritts.

Union: Dr. J. A. Jones.

RESOLUTION REQUESTED BY EXHIBITORS.

Dr. LEONARD. Mr. President, I desire to offer the following resolution of the exhibitors at this meeting:

Whereas, Dr. Wm. H. Gelston has shown such faithful and impartial activities toward the exhibitors, to make the forty-eighth annual convention of the New Jersey State Dental Society a success, displaying at all times unselfish zeal and tireless labor in their behalf; therefore be it

RESOLVED, That the exhibitors do hereby tender to Dr. Gelston a vote of deep appreciation and thanks, together with the assurance of their continued best wishes and endorsement.

This is signed by forty-nine exhibitors.

On motion of Dr. LEONARD, the resolution was unanimously adopted by the convention.

Dr. GELSTON. Mr. President, I deeply appreciate the kindness embodied in this resolution, signed by the exhibitors of this convention. There is nothing that would repay me more than that. I hope that everything I do during the remainder of this convention will meet with the same reception, and that I shall have the same hearty co-operation that I have had in the past. I sincerely thank all who have had anything to do with this resolution.

On motion the convention adjourned until 8 o'clock.

THURSDAY—*Evening Session.*

President Albray called the meeting to order at 8.30 o'clock.

The PRESIDENT. We are very greatly favored this evening in having with us Dr. I. NORMAN BROOMELL of Philadelphia, Professor of Dental Anatomy and Clinical Dentistry, Philadelphia Dental College, who will read a paper entitled "Dentist or Stomatologist?"

[This paper is printed in full at page 980 of the present issue of the DENTAL COSMOS.]

DISCUSSION.

Dr. W. T. Wyckoff, Philadelphia. I have been very much pleased with and impressed by Dr. Broomell's paper, and being one of the older men of the profession, I am carried back to the time when dentistry was only slightly recognized by the medical profession. In fact, I distinctly remember that upon the night of our graduating dinner a prominent physician, a noted specialist in Philadelphia, made an address in which he

said that he sincerely hoped the time was not far distant when the dental profession would be recognized as a branch or arm of the medical profession. At that time we had great trouble in getting the medical profession to recognize anything that was more than simply mechanical dental work, but by persistent effort on the part of such men as Dr. Broomell and other writers and lecturers in the field of dentistry, the medical and dental professions have awakened to the responsibility and the magnitude of this subject, and today the pendulum has begun to swing the other way. I was glad to see Dr. Broomell caution against its swinging too far, as I think we have become a little crazed on this subject of tooth infection. It has always existed, but in my dental education the principal "bugs" we knew of were bedbugs and potato-bugs. We have heard of infections, but of course it comes a little hard for us older men to take it up and think of those things in the light that they should be thought of. I agree that we should accept this broader sense. There is no doubt in my mind that we should be entitled to go farther than we really have in this matter of oral surgery, because the dentist is better prepared to handle these cases than many a physician, as he has opportunities to more closely observe them.

Dr. Chas. S. Hardy, Newark, N. J. Mr. President, I enjoyed listening to Dr. Broomell's paper very much indeed. I think his ideas are a step in the right direction, and I think that at the present time the medical profession is giving us a great deal of recognition. I think they all appreciate that dentistry today is a part of the medical profession, and I believe that as far as teeth are concerned we are a great factor in the conservation of the health of the people, and of great assistance to the medical men in many instances, in successfully diagnosing and treating conditions which they have formerly battled with and have failed to get results. I hope the time will come, as Dr. Broomell says, when we receive a degree such as D.S. or M.D.S. or some other degree that will put us on a differ-

ent basis. I think the dental profession should push this matter strenuously, as it would not only result in recognition to a greater extent by the public and put us on a higher plane in their estimation, but we would have a better standing with the medical profession as a whole if we had a degree signifying special knowledge of the closely allied dental and medical subjects.

Dr. R. H. Riethmueller, New York City. I was very much impressed with the essayist's paper and its intention, but I cannot help feeling that the question of importance for the dental profession is not so much a change in degree, but a change in the quality of work. Dentistry has branched out into so many specialties that it is practically impossible for a practitioner to be a past-master in all its phases, and each practitioner should strive to perfect himself in the work for which he is best adapted. Take, for instance, the specialty of oral surgery, in which special interest is being taken by a great many practitioners today—no doubt owing to the impetus of the wonderful work that is being done in connection with the war. But even before that time a great many men began to specialize in oral surgery, attracted by the possibility of higher fees.

The medical profession readily saw the tendency of modern dentistry toward specialization, and has fully given it its support and co-operation. A wonderful illustration of the work that is being performed by oral surgeons was given this audience last night by Dr. Aller. What a wonderful task the dentist is now performing in the restoration of human wrecks to a semblance of human appearance and the possibility to continue to live in comparative health and comfort! The war films which we are to see will give us even a clearer conception of the extent of the wonderful work that is done near and behind the firing line, especially by the French, which will not surprise us when we remember the name of Claude Martin, the "father" of "immediate prosthesis."

The dental profession may well be proud of the wonderful services that it

is performing today, and when the annals of this world-war are written, dentistry will surely occupy a very prominent place therein.

Dr. Wm. G. Chase, Philadelphia. This question of stomatology, or the degree under which we work, is a question that has been agitated by the dental profession for a great many years. I can go back to the time (1885) when I was a student in the Philadelphia Dental College, where we treated lesions of the mouth and head under the supervision of Dr. James E. Garretson, whom the older men knew and loved. I know how this subject from one time to another has been brought up, and I agree with the previous speaker that it is not a question of changing the degree conferred upon a dentist, but it is a question of fitting ourselves and preparing ourselves to take the positions we should occupy. We talk about the degree of M.D. What does it mean? Doctor of Medicine. It does not take a man any longer to become proficient as a doctor of medicine than to become proficient in oral surgery or as a dentist. I tell young men to make this, our chosen profession, as illustrious and as great as that of the older profession. I hold an M.D. degree, but I do not put it after my name because I do not practice general medicine. D.D.S. is good enough for me. I think Dr. Broomell means to teach us to broaden ourselves.

Dr. Arthur Zentler, New York City. It seems to me that the essayist intended to make a distinction between "dentist" and "stomatologist," and that the point was to know whether the man who passes the D.D.S. examination must confine himself absolutely to the treating of teeth, as it has been in the past, or whether he may go beyond this limit and engage in the treatment of all the adjacent tissues of the oral cavity.

Possibly in the past years most men have done no more than treat teeth, and it is therefore a question, as has been said here, of their equipping themselves with the necessary knowledge to be able to do that which the degree which they receive implies, whether it be a D.D.S.

or an M.D., D.S., or what not. It means simply that they must realize that their field of treatment starts at the vermilion of the lips and ends at the pillars of the fauces, and that everything that happens in this territory is in the realm of the dentist. If it is necessary for the purpose of mastering the details that the present curriculum be extended, that should be done. If it is in any way thought best that the degree should be changed, that may be done; but this is immaterial—it is the knowledge that matters, and with the knowledge, the ability to obtain results that will warrant us in extending our practice to a wider field.

I believe that Dr. Broomell's intention was to convey the meaning that we ought to do more than we do now and have been doing in the past; that we are stomatologists besides being dentists, and this means that we should be able to treat all the infections or other pathologic conditions of the mouth.

Dr. O. E. Inglis, Philadelphia. The word "stomatologist" was coined by Dr. Stellwagen, who received a great deal of credit for originating the term. The Academy of Stomatology of Philadelphia, was named as it is on account of his coining that word, and some other societies took similar names. The gentlemen who have spoken have practically voiced all that I can say on this subject. Dr. Broomell evidently has made a plea for us to be thoroughly informed on all the conditions of the mouth and be prepared to treat all those conditions, and with that statement I do not know that there is anything more to be said. I think that if we have such knowledge today we then only have to consider whether we have the legal right to use it. In this connection I might say that on one occasion I was discussing the matter with Dr. Wayne W. Babcock of Philadelphia, and asked him how far he thought a dentist was justified in operating upon the different parts of the mouth. He said, "He is justified in going just as far as his true knowledge enables him to go without doing any injury to the patient." I do not see

how we can desire a broader basis than that.

Dr. Broomell (closing the discussion). I have very little to add to what I have already said. My chief regret is that I fear I did not make myself quite clear in my attempt to cover the subject in general. However, I am gratified to note that the discussion has brought out some of the points which I neglected to include in the paper. Some reference has been made by one or two speakers regarding the degree to be conferred, and my words in reference to that were simply a suggestion without even an offer that we change our degree, but simply to conform to the idea that our field of action covered the entire mouth cavity rather than the teeth only. Dr. Riethmueller said what is needed is better training. That is quite true; we all need better training. No matter how well one is trained in college, he may be better trained. But the weakness lies in this—that the average graduate of a medical or dental school does not make a full use of the training he has had. I am quite sure this is true of dentistry. The average young man upon graduating feels that he must make money. Therefore he begins to fill teeth, extract teeth, make plates, etc., because he knows that by doing these things he will be repaid financially; and again, once starting along these lines it is very difficult for him to switch off and broaden out as has been suggested. I am just as guilty as anyone in this audience because I do not practice stomatology in the full acceptance of the term. I have never treated a sinus other than those originating from the teeth. I have never treated any of the general diseases of the mouth—so I am equally guilty with anyone else. Nevertheless that does not say that we should not make an attempt to broaden our field of activity. I was well pleased with the remarks made by Dr. Zentler, because he expressed my thought in connection with the subject. He told us that we should not confine ourselves to operations on the teeth and their immediate environment. We seem perfectly at home operating

directly on the teeth and treating the gingival margin, but when we get beyond this narrow zone we are apt to feel timid and show a lack of interest. I feel gratified in the hope that my treatment of the subject will bear some fruit.

It was moved, seconded and carried that a vote of thanks be tendered to Dr. Broomell and to all who took part in the discussion.

The convention adjourned until 8 o'clock Friday morning.

FRIDAY—*Morning Session.*

The PRESIDENT. The next business in order is the report of the Committee on the President's Address, Dr. Van Gieson, chairman.

Vice-president Wakeley then took the chair.

REPORT OF COMMITTEE ON PRESIDENT'S ADDRESS.

Dr. R. B. VAN GIESON. *Mr. Chairman and gentlemen*,—Your Committee appointed to consider the President's Address submits the following report:

The recommendations contained in the address are as follows:

Recommendation No. 1.

That any member of a local society, or a member of the New Jersey State Dental Society who is not a member of a local society, whose dues are not paid by March 1st of any year be suspended from all privileges of the local, State, or National societies until January 1st of the following year, and unless the arrearage in dues and the next year's dues are paid by that date, he be automatically dropped from membership.

Recommendation No. 2.

That the names of all applicants for membership in local societies be referred to the secretary of the State Society before a candidate can be elected, so that the record of the applicant can be investigated and transmitted to the local society.

Recommendation No. 3.

That the incoming Legislative Committee make a strenuous effort to secure the passage

of legislation exempting dentists from jury duty.

Recommendation No. 4.

That the Legislative Committee be instructed to have framed and enacted an amendment to our present dental law similar to the provision of the New York dental law, declaring it illegal to practice dentistry under a false or assumed name, or under the license or registration of another person of the same name, or under the name of a corporation, association, parlor, or trade name.

Recommendation No. 5.

That in view of the successful prosecution and conviction of illegal practitioners in the state during the past year it would be a timely and courteous action on the part of this society to extend a vote of appreciation to the State Board of Registration and Examination in Dentistry, and also to the Attorney-general for the generous amount of time devoted to this purpose.

Recommendation No. 6.

That the society specify that the terms of officers begin on the 1st day of September following their election.

Your committee recommends the adoption of the above recommendations.

Recommendation No. 7.

That the society discontinue the publication of the *New Jersey Dental Journal*.

Your committee recommends that this recommendation be not adopted, but that the matter be referred to the Board of Trustees, believing that the result of such action will prove satisfactory.

Recommendation No. 8.

That a committee be appointed to make the wording of certain parts of our present by-laws more explicit.

Your committee recommends the adoption of this recommendation.

R. B. VAN GIESON, *Chairman*,
W. F. BARRY,
S. B. GLEASON,
CHAS. FAUPEL,
J. I. WOOLVERTON,

Committee.

On motion the report of the committee was adopted.

Dr. HARDY. I move that the society extend a rising vote of thanks to Dr. Raymonde A. Albray for his services rendered in his work on the *Journal*, and as president of this society.

The motion was seconded and carried.

Dr. HOPKINS moved that the Board of Trustees be authorized to draw up amendments in accordance with the instructions as adopted by the society today.

The motion was seconded and carried.

The President resumed the chair.

Dr. HOPKINS. On the opening day of the meeting we were led in singing by Professor Fithian, and I move that a vote of thanks of the society be extended to Professor Fithian.

The motion was seconded and carried.

Dr. WOOLVERTON. I would like the society to extend a vote of thanks to the United States naval war station at Atlantic City; to Rev. Robert Arthur Elwood of Atlantic City; to Mr. Chas. Richard Williams, and to the essayists and others who have taken part in this convention, and I make that as a motion.

The motion was seconded and carried.

The PRESIDENT. Gentlemen, our business is unfinished. This room will be used for moving pictures until 4 o'clock. I will therefore declare a recess until that hour.

President Albray called the meeting to order at 4.30 P.M.

The PRESIDENT. The first business in order is the election of new members.

Secretary FORSYTH then presented applications for membership.

After disposal of these he read a letter which the society had instructed him to forward to Dr. Truex thanking him for his faithful support of the society, and congratulating him on having attended its annual convention for thirty-five years consecutively.

Dr. MANNING moved that this letter be sent to Dr. Truex, and embodied in the record of the proceedings. (Carried.)

The PRESIDENT. A few days ago, Lieutenant Davis of Plainfield, stationed at Camp Dix, asked me to submit a matter to the society in regard to making the Camp Dix dental infirmary more attractive. I have been there visiting the infirmary. They have everything they want and need to work with—chairs, cuspidors, switch-boards, compressed air, steel cabinets, in fact everything a dentist wants to work with—but the inside of the building is finished in rather a rough manner. It is to be a permanent building. Dr. Davis suggested making the place a little bit more attractive, saying that it could be done if the materials were furnished. They have the labor, and all they need is some paint and some pictures, or something of that kind, to make it more attractive inside. He asked me to present the matter before the society here, and if they are willing to do so, suggested that a committee be appointed to go down there and visit the infirmary, see what was necessary, and take action toward securing it.

Dr. IREDELL moved that such a committee be appointed by this society.

Dr. HARDY seconded the motion, and added the following as an amendment: That the amount of the expense shall not exceed seventy-five dollars.

The motion as amended was carried.

The PRESIDENT. I will appoint that committee later. Dr. Slade desires to submit a matter for your consideration.

Dr. SLADE. There was a little misunderstanding last year on this subject, and it may well be considered again, to determine the viewpoint of the society in regard to the men of our profession in our state who have given up their family, their home, and their practice, and entered into the service of the country. There is a principle of right and wrong, a matter of patriotism, that enters into it, as well as a matter of business. Laying aside the occasion of last year and considering the subject from the present moment, it would be advantageous to consider this.

The thought I have in mind is, first, that these men have given up their busi-

ness; and second, if they return, and happily some of them will return to their practice, it is as little as we can do to put them on their feet, so to speak, just as quickly as possible after their return. In order to do that without any advertising or unethical feature entering into it, it is my thought that it would be well to supervise the method of announcing their return and that the matter might be taken up by this society. My idea is that the society prepare two cards, the first to be used by the society, requesting the dentists in the state to make a list of the patients who have come to their practice who have formerly been patients of the man who has entered the service, and upon the return of the man from the service he be furnished with a list of the patients who have recently been cared for. The society would then prepare a card that would read something like this:

Dr. — announces to the patient in the care of Dr. — that Dr. — has returned to the practice of dentistry in [such town] and on [such street] after being in the service of the country.

This is one card. The other one, to be used by the dentist himself, to be something like this:

Dr. — has resumed practice at — after being in the service of our country.

If the practice is such as warrants it, it will be returned very much quicker than by the dentist coming back and having to go through the slow process that he did originally to secure his patients. A great number of men in our profession would do this, even if we did not take action, but this must be done in a methodical manner, and the National Society may well take it up throughout the country.

I therefore move that this subject be considered at this time by the society, with the view to preparing cards, and that the matter be taken care of at the discretion of those to whom it may be referred.

Dr. TUTTLE. I desire to second the motion. I have had several conversa-

tions with Dr. Slade on this subject, and from what I can gather, his object by the motion is to make it official. If done in that way it would be much better for all concerned.

Dr. TUTTLE. I will add an amendment to my amendment to the effect that we instruct our delegate attending the National Convention to bring this matter up before that body.

The amendment to the amendment was seconded and carried; the amendment was carried, and the original motion, as amended, was unanimously carried.

President ALBRAY. I will appoint on that committee Dr. Slade, Dr. Hardy, Dr. Hirsch, Dr. Clark, and Dr. Tuttle.

I will now call upon our newly elected president, Dr. Geo. W. Wakeley, to come forward to receive the gavel. Before I present it to him I want to say that I thank everybody who has worked with me to make this convention a success. We appreciate the efforts which all the members of the society have made, together with everyone who has had anything to do with the convention. I trust you will all give Dr. Wakeley the same co-operation.

President WAKELEY. I appreciate very much the honor you have bestowed upon me, and I will try during the next year to do everything I can for the best interests of the society.

COMMITTEE ON CODE OF ETHICS.

The report of this committee was presented by Dr. VAN GIESON, chairman, as follows:

The committee investigated the Hanrahan matter, and considered it of sufficient importance to recommend that it be referred to the Board of Trustees for their action.

R. B. VAN GIESON,
C. F. A. HANÉ,
R. A. ALBRAY,
JOSEPH C. HALSEY,
G. L. D. TOMPKINS,
J. W. CURTIS,

Committee.

The convention adjourned *sine die*.

Virginia State Dental Association.

Forty-ninth Annual Session, held at Roanoke, Va., April 29 and 30,
and May 1, 1918.

THE forty-ninth annual session of the Virginia State Dental Association was held in the Hotel Roanoke, Roanoke, Va., on April 29 and 30, and May 1, 1918.

MONDAY—*Morning Session.*

The meeting was called to order Monday, April 29, 1918, at 10 o'clock, by the president, Dr. W. H. Pearson of Norfolk.

Rev. W. H. VIRGIN, Roanoke, opened the meeting with prayer.

Hon. CHARLES M. BROWN, mayor of Roanoke, welcomed the association to Roanoke.

Dr. R. L. SIMPSON of Richmond made the response to the mayor's address of welcome.

Dr. PEARSON then read the President's Annual Address, as follows:

President's Address.

By Dr. W. H. PEARSON, Roanoke, Va.

Members of the Virginia State Dental Association, guests, and friends,—I wish to thank you for the honor in electing me to pilot this association this year, but I wish you to know that the smoothness with which it has been run is due to the faithfulness of those on the committees and the splendid manner in which the members have responded to every call. Again let me thank you.

Just forty-nine years ago there was a small group of men with a great vision, who recognized the importance of their profession and the need of organization for its development, and today this association stands as a monument to them. But let us ask ourselves the question,

Is this monument a completed structure? And we are ready to answer with one accord, No.

In the horrible struggle that is raging in Europe the dentists have done a wonderful work in aiding the wounded. The surgeons realize that without the dentists their operation on the face is not a success. This has been a great impetus in bringing the profession to the attention of the world. Dentistry is beginning to come into her own, and the importance of this specialty of medicine is daily being better realized. What is most looked for, though, is preventive dentistry, and it behooves us as an association and as individuals to keep ourselves informed by study and to give all the assistance we can to the Research Institute, financially and otherwise, as it is through this institution we may hope to solve our scientific questions. The busy practitioner is not able to devote his time to these subjects, and had he the leisure he would not have the facility for doing the work; hence the more important it is for us to lend our influence in the most substantial way.

The movement for dental preparedness is one that merits our hearty support; the profession of our state, I am afraid, has not awakened to the importance of this subject. Let us arouse enthusiasm along this line, that each one of us may have a hand in doing his bit.

ORAL HYGIENE.

This is one of the most important subjects before our profession today.

I believe that last session there was an appropriation authorized by the associa-

tion for use of the committee, but on account of the unsettled condition of the country they have not seen fit to carry out the program as they had outlined.

It is important that this subject be taught in our public schools, and since the majority of the schools have phonographs, would it not be wise for us to get some records bearing a simple lecture on mouth hygiene and have them circulated through the state?

The motion picture is also a very effective manner of reaching the public. There is one thing that stands out very prominently, and that is, that we must formulate some plan by which we can reach the children of the state at the earliest possible moment in a systematic way.

RECOMMENDATION OF AN EXECUTIVE COUNCIL.

During our scientific sessions there is too much valuable time wasted with items of business that could be handled with much more dispatch, and many times with greater advantage to the profession, by a committee in advance of our annual meeting, and if necessary from time to time during the year the chairman could make his report to the association and action on the same be taken in a few minutes, thereby giving us more time for scientific work.

I recommend that an executive council be chosen, or that the membership of our Executive Committee be increased to eight or ten, and they be empowered to transact the business of the association.

Our meetings so far as the financial part is concerned are run in a very haphazard way. I do not wish to reflect on any who have had charge of the sessions in the past, for I realize that what has been done was, to the best of their knowledge, for the interest of our association and the profession at large. However, we should adopt a more businesslike method of handling the situation, and the committee and presiding officers should know what to count on. I recommend a budget system, and that the Ex-

ecutive Council or committee be empowered to put such a system in operation in the future.

POSTGRADUATE MEETINGS.

Next year will be the fiftieth anniversary, and let us celebrate by having a real postgraduate course. Our lectures from the celebrated men who meet with us each session without remuneration have given us some valuable theoretical training, but we are to a great degree neglecting the technical skill so essential for good dentists.

Now, in order to put this course in operation, it will mean that we must make a financial sacrifice. I believe it will require at least twenty dollars besides the regular dues of the association; however, this can be worked out by a committee. Oklahoma State Society is the most active body in the United States today, and they have had a very successful course this month. They have been the first to blaze the way, and while Virginia has neglected to take her lead we can be the next to follow.

I recommend that we hold our next session at the Virginia Medical College, Richmond, where we can get every facility for such a course, and that we be in session one week in spring or fall at such time as can be arranged.

In closing I wish to thank the essayists and clinicians for the sacrifice they have made in coming such long distances to help make our meeting a success. I trust you will feel well repaid, and we extend to you the privilege of the society and a hearty welcome to our state.

May I repeat in closing that we are delighted to have you with us?

The following were appointed as a committee to consider the President's Address—Drs. W. H. Street, Richmond, Wm. Pilcher, Petersburg, and J. P. Stiff, Fredericksburg.

Dr. PEARSON then called attention to the fact that the payment of dues was in order at this time, and stated that the treasurer, Dr. W. M. Sturgis of Marshall, was ready to receive dues.

Dr. STURGIS explained that the dues of the society were five dollars, two dollars of which were sent to the National Dental Association as dues and for the *Journal*, and one dollar to the National Research Institute. He further explained that membership in the National Association ran for the calendar year; so that if the dues were not sent until November, the membership in that body would expire on December 31st. The person would retain membership in the state association after that time, but would not be a member of the National. To correct this, he suggested that instead of paying dues at the annual meeting, the members of the Virginia Association pay their dues in January. This would save a great deal of trouble, and would insure each member's receiving the *Journal* of the National Dental Association, which he considered most valuable.

After the transaction of some minor business,

Dr. PEARSON called for the reports of committees.

Dr. HARRY BEAR reported for the Oral Hygiene Committee, in the absence of its chairman, Dr. Guy R. Harrison of Richmond, who was in the United States Medical Service, having been called away to camp too suddenly to prepare his report. Dr. Harrison had asked Dr. Bear to extend his greetings to the members, and to report that the committee had decided that the money appropriated at the last meeting could not be spent this year, owing to pressure of circumstances and unusual conditions prevailing. As much as possible, however, had been done through the State Board of Health, of which Dr. Harrison is a member. He had got the field men to canvass the different sections of the state, and had equipped each with a set of slides and a set of charts showing various mouth conditions. Dr. Harrison and others had also been lecturing through the School of Social Economy and the Visiting Nurse Association. As much as possible had thus been done in the field of Oral Hygiene.

Dr. J. M. LEWIS of Richmond, a member of the Dental Legislative Committee, called attention to the case of a retired practitioner who proposed to act in contravention of the law, and who had been notified on behalf of the committee that he would be opposed.

Dr. M. B. RUDD moved that a vote of thanks be given to Dr. Lewis and Dr. Hoggan.

The motion was seconded and carried.

Dr. STIFF made a motion that in future no clinician be allowed to come to the state without the approval of the president of the association.

Dr. J. E. APPLEWHITE of Newport News, seconded the motion as Dr. Stiff had made it, but suggested that this be done with the approval of the Executive Committee, instead of the president.

Dr. HARRY BEAR said that the president was usually the spokesman for the association, and suggested that it would be better to make it "the President and Legislative Committee."

The motion as amended was seconded and carried.

Dr. R. H. WALKER, Norfolk, chairman of the Clinic Committee, asked whether the members would rather have the clinics held in the progressive order or not. He explained the relative advantages and disadvantages of each method.

It was moved and seconded that the clinics be progressive. After a short discussion, during which the President referred to the successful progressive clinic held at Norfolk in the preceding year, the motion was carried.

The association adjourned at 11.45 o'clock.

MONDAY—Afternoon Session.

The meeting was called to order by the president, Dr. Pearson, at 2.45 o'clock.

He then introduced Dr. FREDERICK BOGUE NOYES of Chicago, Ill., who de-

livered a lecture on the subject of "The Pulp and Peridental Membrane."

[This lecture is not published for the reason that no revised manuscript was received from the lecturer.—Ed.]

Dr. W. H. STREET of Richmond, suggested that as there was nothing scheduled for the evening, a patriotic meeting might be held, and asked that a committee be appointed to arrange for it.

Dr. PEARSON appointed on this committee Drs. Street, Rudd, and Stiff.

An Illustrated Talk on the Work of the Preparedness League was then given by Dr. J. A. C. HOGGAN of Richmond.

Dr. W. M. STURGIS made a motion that during the continuance of the war those members who had volunteered or been drafted and had gone into active army service be relieved of the necessity of paying their dues to the association.

The motion was seconded and carried.

Adjourned at 5.30 o'clock.

Patriotic Meeting.

A stirring patriotic meeting was held in the evening, lasting from 9 until 10.45.

The principal speaker was Dr. T. B. Hill, who had been in Corea for a number of years as a missionary, and was then home on sick leave, and had been taking an active part in war work.

Other addresses by members of the association followed, at the close of which it was announced that \$3750 had been subscribed for Liberty bonds.

Dr. HILL then closed the meeting with prayer.

TUESDAY—Morning Session.

The meeting was called to order at 10.15 o'clock, the president, Dr. Pearson, in the chair.

Dr. Pearson introduced Dr. STEPHEN P. MALLETT of Boston, who presented a paper entitled "Procaïn for Dental Operations."

[This paper is printed in full at page 966 of the present issue of the DENTAL COSMOS.]

DISCUSSION.

Dr. J. M. Lewis, Richmond. There are just a few questions I should like to ask about this method and some of the suggestions Dr. Mallett makes. I have used some of this anesthetic, and have had pretty good success. I notice that he says that procain is seven and one-half times less toxic than cocain. Are these conclusions not drawn from experimental work on animals, and was it not brought out and proved at the National meeting in New York that in human beings it is many times less toxic than that? In fact, I have never read an authentic report of a death from the use of procain, although there may have been some such deaths.

Dr. Mallett mentioned limiting the suprarenin content of the injection. I think the most universal success the men who are trying it have had has been with the F and E tablet combination. The E tablet alone produces too great an anemia, but with the E and F combination, we get an ideal combination and bleeding enough for the blood-clot to be formed, with no danger of "dry socket" after extraction.

Then he mentioned absolute alcohol in sterilization. I wonder whether he has had any trouble from precipitation from the metal part of his syringe in absolute alcohol, and has used glycerin to prevent it. This necessitates boiling before using; but then, personally, I always like to boil my syringe, solution cup and solutions. This does away with any chance of injection of alcohol along with the solution. Temporary paralysis of the nerve is sometimes caused by such an accident.

Then I want Dr. Mallett to speak of the advantages of Ringer's solution as against plain normal salt solution.

There is another thing that I should like to ask. I see that he mentions the untoward effect of the suprarenin content. The time of injection will control that somewhat. If in deep anesthesia

at least a minute is taken to make the injection of the solution, one will get less of that feeling of oppression and trembling in the extremities that Dr. Mallett mentions.

Then he speaks of sterilization of the field of injection, and also the pain from the needle. Dr. Riethmüller suggested, for the sterilization and anesthesia of the field of injection, a saturated solution of menthol in benzol added to equal parts of iodine and aconite. Refrigeration gives a temporary local anesthesia, and does away with the pain of the needle and the necessity of using nitrous oxide and oxygen.

I have had some untoward effects in this method of anesthesia. The worst was a hematoma from injection. This, however, took care of itself, and these minor accidents need not cause uneasiness if you have done a sterile operation.

The after-pain in ordinary cases I do not consider, because it is from the wound, and can very readily be controlled.

Dr. Mallett speaks of fainting. I have never had that occur. I wonder whether it could have been caused by the effect of too great adrenalin content on brain circulation, and shall be glad if the doctor will take up this question.

Dr. Mallett. In regard to procaine being seven times less toxic than cocaine, I will say that this has been ascertained by experiments on animals. I do not believe that anyone has experimented on human beings in that respect. It is something that will have to be determined in the future. It certainly seems to me to be seven times less toxic.

Dr. Lewis. I mean that in clinical cases it is even less toxic than seven times. Has there been a recorded death from novocaine?

Dr. Mallett. I have not heard of any, and if there were, I feel certain that it is not the fault of procaine. I have studied the drug, and know that it is reliable and safe if carefully used. It keeps, it boils, and can be used in larger quantities than cocaine. I sometimes think that it is not as strong an anesthetic as cocaine in the form of tablets

used for pressure anesthesia, as it does not seem to take effect as readily. I think there are cases in which we should limit the amount of suprarenin, particularly in anemic people. These are cases that have to be determined by careful study, observation, and by considering and inquiring into the past history of the individual. A keen, experienced mind can quickly determine the dosage of procaine and suprarenin. There are a few cases in which I have refused to inject procaine, preferring some other anesthetic, but it is very seldom necessary. I do not think much of the use of glycerin, because it makes such a gummy solution with the alcohol, and it is difficult to keep the instruments what I call clean. I did use glycerin for about six months and gave it a fair trial, but have eliminated it entirely. I do not know of any better way than to sterilize the syringe by boiling, being careful to bring it slowly to a boil, beginning with cold water, and after allowing it to cool slowly, wipe in sterile oil and place in absolute alcohol. I do not think there is any advantage in the use of Ringer's solution. I have used Ringer's solution, and will say that I personally prefer normal salt solution, as I have had perfect results with it, and consider the added medicines in the Ringer solution unnecessary.

I think one should be careful in injecting, particularly on the palatal side of the jaw. The injection should be made much more slowly than on the buccal. The buccal injection may be made quite quickly, at least as fast as the tissues will take up the solution, and in the "puffing" method the injection is quite fast. In conduction anesthesia we have heard many men suggest the movement of the syringe back and forth, to avoid injecting into a vein, and although I think there is no objection to it, yet I consider it unnecessary if one has the mouth wide open and the field of operation well exposed. With a positive understanding of the anatomy of the parts, the straight, moderately slow injection is best. I think very often there is too much time taken, thereby causing un-

easiness of the patient and liability to break the needle.

I have not used anything but iodine, iodine and aconite, or campho-phénique as a sterilizing agent on the field of operation.

Canker spots often occur at the point of injection. As a rule I warn patients that they are likely to have sore spots, and should keep the mouth as clean as possible and visit me the next day. I advise the use of Dobell's solution or some antiseptic mouthwash. I have seen some severe cases of inflammation at the point of injection. I consider fainting caused by cerebral anemia untraceable.

Dr. Lewis. Have you had it much where you used a strong suprarenin solution?

Dr. Mallett. Yes, I have had such trouble where I used too much adrenalin or suprarenin. Some years ago I used E tablets entirely and experienced considerable trouble. I think that the E and F tablets should be used in combination, even in cases of extensive operations, and prefer to use more of such a solution than to use the E tablets alone.

Dr. F. R. Talley, Petersburg. I want to make a suggestion. Dr. Lewis said glycerin gums the investment and is hard to get off. I overcome that by having on my table an ordinary round holder of glass arranged on the side of the wall. I have a shaker such as is used in soda fountains in making milk shakes. The syringe is made of thin glass. I have a heater for boiling water. Putting the syringe down in boiling water dissolves the glycerin and alcohol. I have used the same syringe for eighteen months, and have never broken it. By using this apparatus you have perfect radiation, and the glycerin and alcohol can be removed by boiling.

Dr. Mallett. Glass barrels with plungers are very difficult to obtain. In my opinion, the Fischer syringe is the best, and extreme care must be taken when it is boiled, bringing the water slowly to a boil and allowing it to cool slowly, otherwise the glass barrel is easily broken. Therefore it is in my opinion better not to boil or place the

syringe in hot water but once a day for ordinary work. Seventy per cent. alcohol is the best sterilizing agent, but if one uses extreme care to always leave a little solution in the syringe after injecting, then after expelling the remainder of the solution and removing the needle, the syringe can be rinsed in sterile distilled water and placed in absolute alcohol. In this way we avoid the use of glycerin and other gummy agents, and obtain perfectly satisfactory results. Glycerin is all right, but unnecessary.

Dr. Talley. It does not corrode so much.

Dr. Mallett. It is all right, but I get more satisfactory results with plain alcohol, and do not like the feeling of the glycerin.

There is a combination of three drugs that I have found very efficient as a dressing agent after oral surgical operations, particularly after impactions, root amputations, etc., which I would like to suggest that you give a fair trial, and let me know what you think of it. The preparation is as follows: Equal parts of chloroform, liquid petrolatum, and guaiacol, with as much powdered iodoform added as to suit the individual. It is preferable to use the iodoform gauze, saturating it in the solution, and then absorbing the excess of what one thinks is sufficient for the particular case under treatment. I have found that the patients have comfort, are free from after-pain, and infection is prevented by the use of this solution.

The President thanked Dr. Mallett for coming to the meeting and reading his paper.

Dr. W. H. STREET of Richmond, chairman of the Committee on the President's Address, read the report of the committee, which was as follows:

REPORT OF COMMITTEE ON PRESIDENT'S ADDRESS.

We, your Committee on the President's Address, respectfully commend his recommendations with regard to the subject of oral

hygiene, and further suggest that the Committee on Oral Hygiene be particularly and carefully selected to secure those interested in the subject who will give their time and attention to the matter throughout the year, realizing that there is nothing of greater importance to our profession today.

We recommend the appointment of this committee at once, in order that a meeting may be had and plans formulated while this association is in session.

With reference to the second point in our honorable President's address, we concur with him that too much time should not be consumed in detail: such should be handled by the committees, but nothing should be done to discourage free discussion and debate on all subjects.

We do not think there should be any change in the plan of the election of the Executive Committee at this time, or that the number of the committee should be increased.

We recommend, however, that a committee be appointed to be known as the Supreme Council, composed of five members, one member to retire each year, the new member to be appointed by the president. We feel that the Council should be men of experience, deeply interested and enthusiastic, who shall have in heart and head the affairs of the association throughout the year and from year to year. That they should keep in touch with all matters of the association, and be an advisory body to the entire membership. Such committee shall in no way interfere with any of the committees, but shall be to them both soul and Council.

We enthusiastically recommend that part of the address dealing with a postgraduate course, and suggest that a committee be appointed to work out the details so far as possible and report at this session.

In conclusion, your committee commends the able address of our president, and appreciates the unselfish work he has consistently done for the welfare of the Virginia State Dental Association.

Respectfully submitted,

W. H. STREET.

WM. PILCHER,

J. P. STIFF,

Committee.

It was moved and seconded that the report be adopted. After some discussion as to whether the committee of members in the different districts of the state, as recommended in the report, should be appointed by Dr. Pearson or

by the incoming president, the motion to adopt the report of the Committee on President's Address was carried.

Dr. PEARSON explained his idea as to what the postgraduate course at the next meeting of the association should be. He thought that there should be several good men to give it, the number depending on how many intended to take the course. It would cost a good deal more than the small fee paid in the association. His idea was that each member should signify which of the several courses he wished to take. If there were four of these, they could be given for four consecutive years, so that each man might have an opportunity to take each course.

Dr. PEARSON appointed Dr. J. A. C. Hoggan, Richmond, Dr. M. B. Rudd of Richmond, and Dr. C. B. Gifford of Norfolk, as members of this committee, with instructions to report at the evening session.

As members of the Oral Hygiene Committee, the President appointed Drs. R. D. Phelps, Lynchburg; J. E. Applewhite, Newport News; H. L. Smith, Charlottesville; C. A. Newland, Wytheville; W. H. Street, Richmond; F. V. Clark, Roanoke; W. H. Savage, Clifton Forge, and J. M. Lewis, Richmond.

Dr. HOGGAN moved that the duties of the Council be defined and incorporated in the by-laws.

The motion was seconded.

Dr. TALLEY offered as an amendment that the report of the committee be adopted. Dr. Hoggan accepted the amendment.

The amended motion was then carried.

Dr. W. M. STURGIS presented the Report of the Treasurer.

On motion, duly seconded, the Treasurer's Report was received and filed.

The Secretary announced that at the Patriotic Rally, held the preceding evening, thirty-one subscriptions had been received, amounting to \$4050.

Dr. STREET made a motion that the association invest \$300 in Liberty bonds.

The motion was seconded and carried.

Dr. STREET then made a short address in which he asked for additional subscriptions to bring the amount up to \$5000, it then being \$4350.

Dr. B. T. BLACKWELL presented the report of the Executive Committee.

On motion, the report was adopted.

Dr. WALKER nominated Dr. Campbell and Dr. Stiff to be recommended to the Governor as members of the Board of Examiners.

Drs. Walker and Potter were also nominated. The nomination was seconded.

It was moved and seconded that the nominations be closed. The motion was carried, and they were chosen.

Dr. STREET announced that the \$5000 subscription to the Liberty loan had been secured. (Applause.)

Adjourned at 2 P.M.

TUESDAY—Evening Session.

The meeting was called to order by Dr. Pearson at 8.30 o'clock.

Dr. E. U. POTTER of Roanoke, read the report of the Board of Examiners.

There being no objections, the report was accepted.

The scientific program was then taken up, and Dr. SAMUEL P. CAMERON of Girard College, Philadelphia, Pa., presented a paper entitled "The Value of Weak Solutions of Formalin for Immediate Root Sterilization."

Dr. HARRY BEAR of Richmond, read a paper on the "Scope of Exodontia."

The association proceeded to the election of new members, and the President appointed as tellers Drs. Sturgis, Street, and C. E. Harper of Danville.

Dr. BLACKWELL read the list of candidates approved by the Executive Com-

mittee, and all the candidates were duly elected.

ELECTION OF OFFICERS.

The next order of business was the election of officers for the ensuing year, which resulted as follows:

President—Dr. S. B. Ward, Bellehaven.

Vice-president—Dr. B. T. Blackwell, Richmond.

Treasurer—Dr. W. M. Sturgis, Marshall.

Recording Secretary—Dr. Geo. F. Keesee, Richmond.

Assistant Recording Secretary—Dr. Harry Bear, Richmond.

Corresponding Secretary—Dr. W. H. Street, Richmond.

In regard to the Executive Committee Dr. D. R. PHELPS of Lynchburg made a motion that the constitution be changed in such a way that the chairman would be dropped each year, and a new man elected, the second on the list for the preceding year becoming the chairman for the ensuing year, and each member of the committee moving up one place.

The motion was seconded and carried by a rising vote.

It was decided that the society could not act under this amendment until the following year, however, and that three members of the Executive Committee would have to be elected on this occasion.

J. A. C. HOGGAN of Richmond was nominated and elected as chairman. The following were nominated and elected as the other members of the committee: Dr. C. W. Beauchamp of Charlottesville, and Dr. W. G. Delp of Rural Retreat.

Dr. J. A. C. HOGGAN made a motion that a committee be appointed to divide the state into specific districts, to represent component societies, and have a president of each society, so that it may form a working organization for the accomplishment of matters that concern the dental profession.

The motion was seconded and carried.

On motion, duly seconded, a vote of

thanks was given to the official stenographer, Miss Lulu Gay of Philadelphia.

A motion was carried to appoint a committee to draw up resolutions concerning the death of Dr. J. B. Pressey of Hampton, and the President appointed Dr. Campbell as chairman, with power to ask two other members to assist him.

The SECRETARY made a motion that the association authorize the treasurer to buy three Liberty bonds with the three

hundred dollars voted for this purpose, and be the custodian of these.

The motion was seconded and carried.

Dr. PEARSON said that he would appoint the secretary as a committee of one to attend to the matter.

Dr. PEARSON then presented to the society the newly-elected president, Dr. S. B. Ward, who expressed his appreciation of the honor conferred upon him.

The association then adjourned.

Mississippi Dental Association.

Forty-third Annual Meeting, Meridian, Miss., April 16 and 17, 1918.

TUESDAY—Morning Session.

The forty-third annual meeting of the Mississippi Dental Association was called to order at 9.30 A.M., Tuesday, April 16, 1918, by the president, Dr. T. B. Wright of Hattiesburg, in the Great Southern Hotel, Meridian.

The meeting was opened with prayer by Dr. DEB. WADDELL.

The Hon. J. M. DABNEY, mayor of Meridian, gave the welcome address, which was responded to by Dr. A. B. KELLY of Yazoo City.

Dr. M. B. Varnado, vice-president, in the chair, introduced Dr. T. B. WRIGHT, the president, of Hattiesburg, who then read the annual address, as follows:

President's Address.

By T. B. WRIGHT, D.D.S., Hattiesburg, Miss.

Fellow-members of the Mississippi Dental Association, ladies and gentle-

men,—I am gratified to see so many present, and welcome you most cordially to this the forty-third annual session of the Mississippi Dental Association. Our "destiny" is "onward," and this being true, it means that our efforts must be united for every good work.

We meet today in Meridian, the Queen City of our state. It is not our first visit to this city, and it affords us a peculiar delight to be here again, to exchange greetings with those to whose generous hospitality we are not strangers, and with whose good-will we have before been signally honored. We have the most pleasing surroundings, with every facility for our meeting, and a program filled with clinics and ideas from the very best men in our profession. These we hope may all tend to inspire those in attendance so that this meeting shall become a memorable one.

Among the vicissitudes incident to life no event could have filled me with deeper appreciation than the preferment so generously conferred upon me by my asso-

ciate members at the last session of this body, and I would be remiss indeed on this occasion did I not extend to you my grateful acknowledgment of the honor which it seemed your pleasure to bestow upon me. Especially do I wish to express my deep sense of obligation to the Executive Committee, the officers, and the various committees of the society for the faithful work done in arranging for this meeting.

It is not my purpose to enter into a lengthy discussion, but it has been my ambition to make some real contribution to the association, and I have tried to make some study of the problems which are before us, and which must be solved by those who come together in meetings of this kind. So, realizing the responsibility resting upon the presiding officer, and being as I am deeply concerned regarding our profession at large, and our own state organization in particular, I wish to call to mind a few thoughts for your careful consideration.

MEMBERSHIP OF THE SOCIETY.

It is gratifying to note the work done by our Membership Committee. They have put forth earnest effort and have done well. Yet we are struggling on with a membership of less than one hundred and fifty when there are many more efficient, ethical dentists in our state who should be working with us, and who should be made to realize that they should be contributors to our meetings, and that by attending they would, no doubt, receive many good ideas. It should be our aim and determination to make every dentist of good standing recognize that there are real benefits to be derived from meeting each year with his state association.

I am sure I voice the mind of many, yea, all present, when I appeal for some plan to be submitted whereby we may largely increase our membership. There are many demands being made upon our profession today; we are making wonderful strides forward, difficult problems

will be met, and we must prove ourselves fully abreast of progress in all lines. It behooves us, then, to arouse ourselves to the realization of this greater responsibility that is being placed upon us, and of which we are proud. I am convinced that we shall prove ourselves equal to the task, for we know we must be "up and doing" in the very best service we can render our fellow man. We must co-operate, we must preach the doctrine of progress and good-will among our fellows, and bring them into vital sympathy with our organization, and get their help.

A body or an organization of this nature never stands still; it either progresses or retrogresses. It is not necessary to ask what the trend of this membership will be, for there is no reason why we should not move forward and enlarge, and become one of the best state dental societies of the country.

ETHICS.

It is the duty as well as the desire of the members of this organization to feel and to make known that we hold to the maintenance of *ethical dentistry*. We stand for fair dealing with the public, yet as we press forward in our professional career, struggling hard to gain firmer foothold as we march onward, we are reminded that there are always some disagreeable tasks, not only in our daily practice, but along the route, as we meet those in our own vocation who are not willing to compete fairly with their brother practitioners, but humiliate the profession and violate its ethics which mean so much. I refer to the flagrant advertisers. They know better, but wilfully choose this course, and it is an injustice to the dental profession, and oftentimes an imposition upon the public. They need to be shown the error of their way. It will require delicate study, of course, to determine the means by which we may influence these men against such acts, and induce them to join with us in upholding our profession to its true standard, rather than to debar them be-

cause of their lack of regard for ethics. Any vocation is better for its ethics—code or codes if you please. Let us now strive to correct this evil, and go about it in such a way as to obtain results. Let us put forth concerted effort to win these men to a real appreciation of the genuineness of the *ethical dental profession*.

At this point I would suggest that a committee be appointed by the incoming president to prepare and read a paper to the medical profession at the next annual meeting of their association, accompanied by a copy of our national code of dental ethics, which has been adopted by this society. Impress upon them that we are striving to work hand-in-hand with them, and endeavoring to maintain our vocation upon the same high plane with their own noble profession, of which we are indeed a branch, a specialty, and that we deserve and should have sympathy and co-operation from them. Each year these two professions are becoming more and more closely allied. It has been said that the next step in preventive medicine must come from dentistry. It is a well-known fact that scientists have all along, but more recently, traced the cause of many diseases and ills to the condition of the mouth and teeth; therefore our professions should work together in mutual interest and understanding. Let the medical profession realize that we stand for genuine, ethical, conscientious service and the best good to humanity.

It is known that many mental disorders are traceable to neglect of the oral cavity. This is an acknowledged fact, and yet I say, and it is with shame I acknowledge it, that our poor unfortunates housed within our insane hospitals, for whom our state stands guardian, have no regular dental services. Should not the state employ a dentist to relieve their suffering? Is he not a necessity? Our insane hospitals as well as other eleemosynary institutions should have efficient and conscientious dentists on their professional staffs. I would suggest that our Legislative Committee emphasize

this fact strongly in their recommendations to the Legislature, and insist that it be given attention at the next session.

PUBLICATION OF THE PROCEEDINGS OF THE SOCIETY.

Each year we expend from \$150 to \$200 for the preparation and publication of our proceedings in pamphlet form. It has occurred to me that we might well discontinue this expenditure. I have been in correspondence recently with the editor of the *DENTAL COSMOS*, and he assures me that he is not only willing to have our proceedings, in the main, appear in the *COSMOS*, but will be glad to sustain the cost of making the report. In this way we could still have our minutes, and the fund heretofore used for this purpose could be placed in the treasury subject to call for greater benefit to our organization. In a short time this fund would accumulate, and enable us, as we have often wished, now and then to have men of national reputation come before us in a series of lectures or clinics. This would be a schooling to us, and I firmly believe would be a means of increasing our membership.

I would recommend that hereafter we make our sessions longer during the day, and eliminate the night sessions. This will afford us, after a day of hard study, work, and discussion, time for recreation, good-fellowship, and rest. We would then return to the convention hall the next morning refreshed, with minds wide awake and energies alert to derive the most benefit from each clinic and paper read. The Program Committee could keep this in mind in arranging the program. Larger organizations have successfully handled their programs in day sessions. I believe we would welcome the change, and after trying it once, adopt it permanently.

ARMY DENTAL LEGISLATION.

I would feel that I had not done my full duty were I to close this address

without giving voice to the appreciation we feel toward our National Congress for the recognition given the profession of dentistry. Of course we are all familiar with the act passed by Congress October 6, 1917, wherein it is enacted that the dental corps of the regular army shall consist of commissioned officers, with rank, promotion, etc., on the same basis as now exists or may be provided hereafter for the medical corps. Of this recognition we feel appreciative, as we have long realized it is a justice due us. Knowing and studying, practicing, and coming in contact, as we do many times each day, with the advantages to be gained in health from a mouth and teeth well kept and in perfect condition, we could not expect less of our lawmakers.

When on April 6, 1917, in an extra session, Congress declared that a state of war existed between the United States and the Imperial German Government, authority was given our President, commander-in-chief of the army and navy, to use all his power toward preparing a defense against imperialism. Our worthy President felt that in order to carry on the war successfully it was necessary that all our forces, professional, business, and men from every vocation, be called to service.

The strength of an army is its man power, and as someone has said, "No man is stronger than his teeth," since his health depends to a large extent upon the condition of his teeth. The dental profession, indeed, forms one of the greatest resources for making our army efficient. There are many dentists in the service. Many were in the regular army, and there are many who have enlisted since war was declared; many are working in cantonments now, and still there is need for more—just as there comes the call for more medical men, more nurses, and more fighting men. We can not all go to the battle-front, but we can all do our bit. There are liberty bonds to be purchased, thrift stamps in abundance; our obligation to protect the practices of our fellow practitioners who have gone, opportunity to join the Preparedness League of American Dentists

—something for all of us to do in the service.

We are at war! it is *our war*. Mr. Wilson asks that our every resource for winning the war be utilized. There is every reason for us to face this problem seriously, and to be unflinching in our determination to solve it aright. We need not fear the future. Why should we? is there any good reason? We are blessed in that the rivers of blood are not flowing in our own land. While we stand on this side of the broad Atlantic and look in one direction we see abundance smiling upon the fields, with all the blessings earth can afford; the sun rises each morning to give brightness, and shed its light upon all habitations. So far as battle is concerned all is quiet, a picture of peace!—while if we turn a listening ear in the other direction we can almost hear the thunder of cannon and wails of suffering. Could we but see afar our eyes would rest upon harrowing sights, hunger, devastation, and death—a picture of war, relentless, cruel, manacled with horrors. It is ours to *give*, to *send*, to *go*. We know that the man nearest perfect is he who gives himself to the activity of the most noble impulses of his mind and soul, who employs his best efforts for good—the one who throws himself into the midst of work for humanity, forgetful of self, and thoughtful only of what the reaction of his beneficence will mean to the world. This is where our profession can prove its most earnest and highest motive. We are not slackers; it is not time for these, nor "hagglers," nor critics, but we are men bound by honor and our own impulses to join for the right. Upon the one hand stands the Kaiser and everything representative of monarchy and hatred; upon the other hand, the United States and her allies, in order that the world may have liberty. 'Tis easy to make our choice, for

We are set where the ways are met
To lead the waiting nation on;
Not for our own land is Freedom's
flag unfurled,
But for the world.

The Chair appointed Dr. J. N. C. Moffat, Dr. C. A. Roy, and Dr. G. F. Haynes as the Committee to report on the President's Address. The report was as follows:

REPORT OF COMMITTEE ON PRESIDENT'S ADDRESS.

We, the Committee on the President's Address, beg leave to submit the following report:

First: We consider this address a splendid appeal to the nobler qualities of manhood, and a just tribute to the patriotic spirit so unanimously evinced by the membership of our profession.

Second: The suggestion that we renew our efforts to enlarge our membership is certainly a timely one, as our secretary's books show an actual loss in membership, but as no specific plan was offered, we leave the question open for discussion.

Third: With reference to the "flagrant advertiser," as no means has ever been found to reach these men as a class, we feel that it would be a waste of time to take up the question in open session, although we feel that each community should be encouraged to use every effort possible to combat this evil.

Fourth: The suggestion that we authorize the appointment of a committee to prepare a paper to be read at the meeting of the Medical Association, together with our code of ethics, meets with our approval, and we recommend its adoption.

Fifth: We favor the suggestion that our Legislative Committee ask for an act providing a dentist on the staff of our Insane Hospital.

Sixth: With reference to the suggestion of discontinuing the practice of printing the Proceedings of the association in pamphlet form, we find, after reading some of the correspondence between our president and the officials of other state organizations, together with that of the Editor of the DENTAL COSMOS, that the idea appeals to us very strongly.

Seventh: The recommendation for daylight meetings really meets with our approval, when possible to so arrange them, but we doubt the wisdom of making any official changes along that line. Therefore we do not recommend its adoption.

Eighth: We approve the voice of appreciation to our National Congress for what was done in our behalf, and recommend that a vote of thanks and continued allegiance to

the "greatest nation on earth, the U. S. A.," be spread on our minutes.

Respectfully submitted,

G. F. HAYNES,
J. N. C. MOFFAT,
C. A. ROY,

Committee.

It was then moved and seconded that the report be received and spread on the minutes.

It was moved and seconded that the President's address as reported by the committee be discussed.

Dr. CLEMMONS of Meridian discussed the pamphlet form of proceedings and also the night session. He advocated that the proceedings should be published as formerly.

Dr. SMITH discussed the question of dental services to the Insane Asylum.

Dr. W. R. WRIGHT moved that the incoming secretary and treasurer be instructed to furnish the proceedings to the DENTAL COSMOS, a copy to be kept for the archives at Jackson. (Motion carried.)

Dr. KELLY moved that the first three articles of the President's address be adopted as read. (Motion carried.)

Dr. KELLY moved that the fourth clause in the President's address be adopted. (Motion carried.)

Dr. KELLY moved that where other state institutions have physicians, we ask that a dentist be added. (Motion carried.)

The question was referred to the Legislative Committee.

The seventh article, in regard to night sessions, the committee moved be not adopted. (Motion carried.)

The eighth article was on motion adopted.

Dr. WRIGHT, in the chair, extended a cordial greeting to visiting dentists.

Dr. W. R. WRIGHT of Jackson moved, in the case of members who have offered their services to the nation, or who may offer them, that their dues be remitted. Referred to the Board of Trustees.

The next order of business was reports of committees.

Dr. BRUNSON, chairman of the Executive Committee, reported that Dr. Kelman and Dr. Phillips would not be in attendance.

Dr. BEAVERS, chairman of the Clinic Committee, announced that the clinics would begin promptly at 2 o'clock Tuesday afternoon.

Report from the Clinic Committee was made by Dr. REABAN.

Dr. L. A. SMITH reported for the Honorable Fellowship Committee.

Dr. HAYNES reported as delegate to the National Dental Association.

The association then adjourned to meet at 2 P.M.

BOARD OF TRUSTEES.

First Meeting.

Called to order by the chairman.

The following members were present: Dr. C. B. Baker, J. N. C. Moffat, J. F. Brunson, W. R. Wright, A. B. Kelly, W. C. Dennis, L. B. Price.

The Secretary read a letter from Dr. J. F. Colley of Moss Point, asking membership.

The applications of Dr. W. H. Ellis, Midnight; Dr. T. C. Chicester, Lambert; L. R. Butler, Cleveland; Willard F. Powers, Greeneville; W. B. Brady, Lexington; Carlton Kelly, Marigold; J. S. McWilliams, Yazoo City; E. C. Shackelford, Louise; T. K. Barfield, Meridian; Ira W. Williamson, Hickory, reinstatement, were received, and all being properly indorsed were elected members.

Dr. W. R. WRIGHT moved that the members who had enlisted or would enlist in the military service be exempted from dues. (Motion carried.)

Next meeting of Trustees called for Wednesday at 8 A.M.

TUESDAY—Afternoon Session.

The afternoon session was devoted to the following clinics:

Dr. D. M. GARNER, West Point: "Conduction Anesthesia Employing Dr. A. E. Smith's Method, using Apothecin instead of Novocain."

Dr. W. H. REABAN of McComb: "Showing New Inventions, Applications, and Objects of Art."

Dr. S. L. SILVERMAN, Atlanta, Ga.: "Apicoectomy, Root Amputation, and Exodontia, using Conduction Anesthesia. (1) Apicoectomy. (2) Extracting Impacted Third Molar."

Lieut. P. M. FUGLER, D. R. C., Camp Shelby: "The Use of Dental Splints in War Surgery."

TUESDAY—Evening Session.

The meeting was called to order at 8 o'clock by President Wright.

The first order of business was a paper by Dr. CHAS. F. CHANDLER of Montgomery, Ala., entitled "A Comparison of the Different Theories Pertaining to Root-canal Technique," with stereopticon slides.

The next item on the program was a paper by Dr. B. A. BATSON, New Hebron, on "Exodontia."

[This paper is printed in full at page 1006 of this issue of the Cosmos.]

Dr. S. L. SILVERMAN of Atlanta, Ga., gave a lecture and showed slides on "Apicoectomy, Root Amputation, and Exodontia."

Dr. S. W. FOSTER of Atlanta, Ga., read a paper entitled "The Influence of the War on Dentistry and Dental Colleges."

[This paper is printed in full at page 1001 of this issue of the Cosmos.]

BOARD OF TRUSTEES.

Second Meeting.

The meeting was called to order by the chairman at 8 A.M. Wednesday.

Present: J. B. Askew, W. C. Dennis, J. N. C. Moffat, W. R. Wright, A. B. Kelly, T. B. Wright, J. F. Brunson, C. B. Baker, L. B. Price.

A motion was made that the association buy a \$500 Liberty Loan bond, sub-

ject to the vote of the association. (Motion carried.)

Dr. J. F. Brunson was elected chairman *pro tem*. Motion was made and carried that the chairman appoint a committee to select all committees for the next annual meeting.

Applications for membership were reported from W. T. Walker, Brooksville; G. W. Davis, Sumrall; C. S. Williams, Ellisville; W. C. Sandusky, Holly Springs; P. E. Lewis, Pachuta; C. L. Clements, Pontotoc; Doyal Stubblefield, Houston. All being properly indorsed, they were elected to membership.

WEDNESDAY—Morning Session.

Dr. Wright, president, announced as the first item on the program for the morning session a paper by J. M. GUTHRIE, M.D., entitled "The Relation of Nasal and Oral Sepsis to Systemic Diseases and Surgical Conditions Resulting from Focal Infections."

[This paper is printed in full at page 1003 of the present issue of the DENTAL COSMOS.]

The next item on the program was a paper by Dr. C. E. HINES, Memphis, Tenn., entitled "The Treatment of Pyorrhea."

[This paper is printed in full at page 992 of the present issue of the DENTAL COSMOS.]

The following clinics were then held:

Dr. C. F. CHANDLER, Montgomery, Ala., explaining his "Method of Filling Root-Canals."

Dr. H. D. CHIPPS, Corinth: "Amalgam: Its Use and Manipulation."

BOARD OF TRUSTEES.

Third Meeting.

Present: J. F. Brunson, A. B. Kelly, J. B. Askew, W. R. Wright, J. N. C. Moffat, W. C. Dennis, C. B. Baker, and L. B. Price.

Applications of new members as read

before the association: The applicants were duly elected.

Dr. E. A. MAY asked permission to present a bill of expense incurred from work done for the Preparedness League of American Dentists, and also to expend moneys not to exceed twenty-five dollars during the coming year.

Dr. Cooper and Dr. Tillman were elected to fill the places of absent members of the Finance Committee.

Motion was made and carried that the minutes be typed and put in form and paid for by the association.

WEDNESDAY—Afternoon Session.

ELECTION OF OFFICERS.

The order of business for the Wednesday afternoon session was the election of officers, which resulted as follows:

President—M. B. Varnado, Osyka.

Vice-president—W. C. Dennis.

Secretary—W. F. Beavers.

Treasurer—C. B. Baker.

Journalist—R. B. Warriner, Corinth.

Delegate to National Dental Association—W. R. Wright, Jackson; J. N. C. Moffat, alternate.

Place of next meeting—Clarksdale.

WEDNESDAY—Evening Session.

The meeting was called to order by President Wright at 8 o'clock.

The first item on the program was a paper by Dr. J. N. C. MOFFAT, Shelby, on "Conduction Anesthesia."

[This paper will be published in an early issue of the DENTAL COSMOS.]

The next item for the evening session was a paper by Dr. E. A. MAY, Jackson, entitled "The Application of Business Principles to the Practice of Dentistry."

[This paper will be published in an early issue of the DENTAL COSMOS.]

The next order of business was a paper by Dr. G. B. CLEMENTS, Meridian, on "Dental Science and Literature."

[This paper will be published in an early issue of the DENTAL COSMOS.]

A subscription of \$865 was raised for a "progressive clinic" for next year's meeting.

BOARD OF TRUSTEES.

Fourth Meeting.

This meeting took place Thursday A.M.

Present: J. F. Brunson, M. B. Varnado, J. N. C. Moffat, J. B. Askew, C. B. Baker, W. R. Wright, L. B. Price.

Drs. Askew and Varnado were appointed to act on the Finance Committee.

Standing committees for the ensuing year were appointed.

Motion was made and carried that Dr. Brunson be instructed to write Drs. Chandler, Hines, and Brothers, thanking them for their assistance in the program and tendering them compensation for their expenses incurred in attendance.

Application for membership of Dr. T. E. Brent of Laurel was received and accepted.

Adjourned.

THURSDAY—*Morning Session.*

The order of business as announced by the President was the installation of newly elected officers.

The association indorsed the action of the Trustees in regard to the purchase of a Liberty Loan bond by standing vote.

Dr. Brothers of Birmingham and Dr. Hines of Memphis were elected corresponding members.

The association adjourned to meet next year at Clarksdale.

THE DENTAL COSMOS

A MONTHLY RECORD OF DENTAL SCIENCE.

Devoted to the Interests of the Profession.

EDWARD C. KIRK, D.D.S., Sc.D., LL.D., *Editor.*

L. PIERCE ANTHONY, D.D.S., *Associate Editor.*

PHILADELPHIA, NOVEMBER 1918.

EDITORIAL DEPARTMENT

Rip Van Winkle, M.D.

THE *Journal of the American Medical Association*, in its issue of September 21, 1918, devotes considerable space to an editorial discussion of "Dental Bacteriology in Relation to Dental Caries." The article in question seems to be an unburdening of the editorial mind of impressions derived from the reading of K. F. Meyer's paper, "The Present Status of Dental Bacteriology," read before the California State Dental Association in July 1916, and published in the *Journal of the National Dental Association*, vol. iv, p. 966.

A number of years ago it was asserted by the eminent editor of a then well-known medical magazine that "the D.D.S. degree would always be the badge of a partial culture," and the dental

profession was solemnly warned to mend its ways and eliminate this stigma on its professional escutcheon by abandoning its distinctive degree and acquiring that insignia of omniscience the M.D. degree, which at the period referred to was conferred after two short sessions of attendance upon the medical curriculum as at that time constituted. *

Time has wrought changes and improvements in both medical and dental education. Four years of intensive training is now the standard requirement for the dental course, and its curriculum embraces all of the sciences, including bacteriology and bacteriopathology, that are fundamental to the medical as well as the dental curriculum. Medicine likewise requires four years to complete the standard curriculum leading to its distinctive degree. Hence it will be seen that it takes a course of training just as long to properly educate a dental student in the data relating to the mouth and its contained organs as it does for a medical student to acquire a satisfactory knowledge of everything else appertaining to the human organism apart from the mouth.

We are not yet ready to concede that this marked difference in the relative scope of the two curricula of equal length implies any difference whatever of intellectual capacity in the student material concerned with the study of medicine or of dentistry respectively. It does, however, serve to illustrate the fact that, given equal intelligence to start with, a dental student after four years' intensive study of his special field will know more about the data of his profession than the medical student who has been deluded with the belief that he can compass a knowledge of the entire human organism in the same period of time.

And if the foregoing represents the facts of the situation, it will suggest the desirability of a reconsideration of whether the D.D.S. degree is, after all, and relatively speaking, the badge of a partial culture; whether indeed, and again relatively speaking, it is not the M.D. degree that is open to that type of criticism. Moreover, these same factors apparently go far toward explaining the survival of that ancient mental attitude of omniscience as an attribute of the medical mind as an inheritance from the dark ages when the physician knew relatively so much because no one else knew anything in particular about the body and its functions, either in health or disease.

We are impelled to these animadversions by reason of the remarkable conclusions reached by the editor of the *Journal of the American Medical Association* in the issue referred to. He says, with reference to caries and bacteria:

Let it be clearly asserted that the relations of cause and effect are by no means clearly demonstrated in the bacteriologic studies of decay made up to this time. But if one is justifiable, from such somewhat indefinite findings as are presented, in assuming that oral micro-organisms are in some way or to some degree responsible for dental decay, it is logically in order to attempt to eliminate the causal agents.

There are numerous other pearls of oracular wisdom to be found in this same editorial, but what we have above quoted is the most illuminating in its bearing upon our contention as to the obsession of medical omniscience. The editorial quotes Meyer as having pointed out that "Neither Miller nor any subsequent investigator has succeeded in finding any organisms strictly specific for caries." Concerning which we might add that the greatness of great minds is often exemplified as much by what they do not do as by what they do. Miller did not believe there was a specific organism for dental decay. Why should there of necessity be an organism specific for caries? Is there such a thing as an organism specific for fermentation or for putrefaction?

The fundamental difficulty in the way of a medical man, or of a bacteriologist or a laboratory biologist, who tries to solve the problem of dental caries, is that none of these have had a dental training, consequently they have no practical knowledge of the natural history of dental caries nor of its clinical phenomena. They regard it from the same angle of view as they do measles, typhoid, or any specific zymotic disease; whereas all reliable evidence at our command strongly points to the conclusion that dental caries is not a disease in any such sense, but is a process of disintegration of tooth structure analogous to that by which the animal organism is disintegrated after death by saprophytic and fermentative agencies. While normal vital teeth succumb to carious action, so also do those without vital connection with the body, and so also do artificial dentures carved from bone or ivory when placed in a mouth the *locus* of a caries-producing environment.

Miller a third of a century ago *demonstrated* the nature of the relation which micro-organisms bear to the causation of dental caries—the rest guessed about it; and many are still guessing as to the “cause” of dental caries. That is another problem involving the question of immunity and susceptibility, and among other things just the lines of research favorably referred to by the editor of the *Journal of the A. M. A.* as being studied by Meyer, Kligler, Gies, *et al.*; but when a magazine which is commonly regarded as the bell-wether of medical periodical literature in America in this twentieth century and a full generation after the publication of Miller’s classic researches betrays its ignorance of the status of our knowledge of “Dental Bacteriology in Relation to Dental Caries” by suggesting that we may possibly be justified in “assuming that oral micro-organisms are in some way or to some degree responsible for dental decay,” the awakening of Washington Irving’s hero of the Village of Falling Water comes irresistibly to one’s mind, with its mental vacuity as to past events—a condition in the present instance for which two methods suggest themselves as a remedy: either a careful study of Miller’s classic research, or a regular course of study in a modern dental school.

A Correction.

As a result of one of those unaccountable lapses which occasionally overtake the most expert, our proofreader designated iodine trichlorid as an “anesthetic” instead of an antiseptic as was clearly intended in the footnote on page 908 of our October issue. We apologize both to the author and to our readers for this error.

—ED. COSMOS.

PRACTICAL HINTS

This Department specially welcomes the brief presentation by our readers of any novel suggestions or methods which in their own practice have proved to be time-saving or to possess other features of advantage.

Application of Silver Nitrate Solution in Root=canal Work.

By WALTER F. PROVAN, D.M.D., Boston, Mass.

As certain dentists have found difficulty in applying Dr. Howe's silver nitrate solution in root-canal work. Perhaps the method I employ in my practice may be of help to some.

There are several different conditions which may be presented, and these can be met in various ways. In the first place the root-canal in all cases must be cleaned out thoroughly. Next it is necessary to get the silver nitrate solution (solution No. 1) to the apex. Capillary attraction will not take it there if the root-canal is dry, as air will be caught in the upper end of the canal. It is quite difficult to dislodge this air with a smooth broach, and besides, the danger of lacerating the tissue beyond the end of the root is very great.

This difficulty will be easily overcome if a Johnson & Johnson sterile cotton point is saturated in solution No. 1 and inserted to the apex. The point is soft, and will not injure the apical tissue. This will moisten the walls of the canal all the way down. Next, a drop of the solution is introduced in the pulp chamber with a pair of clean cotton pliers. A little careful manipulation with a smooth broach will now aid capillary attraction to draw the liquid to the end

of the root. Allow this application to remain for three or four minutes, and then with another pair of pliers add a drop of solution No. 2. Again use the smooth broach carefully, and wait for three or four minutes more.

Now dry out the canal slightly with another cotton point and add another drop of solution No. 1. To this add a drop of eugenol, and again use the smooth broach carefully. Wait three or four minutes more and then dry out all the excess moisture from the canal with cotton points. Now introduce some chloro-percha on a smooth broach until the root-canal is full, then pack in some gutta-percha points until the canal filling is a homogenous mass, and hard. This can be done with canal pluggers. Flow cement over the gutta-percha, and the operation is completed.

If advisable for any reason the gutta-percha filling can be postponed until a subsequent sitting, in which case the tooth must be sealed tightly, and no other dressing is necessary. If this waiting method is used repeat the application of the silver nitrate solution, as described above, at the second sitting, and then proceed with the gutta-percha filling.

When eugenol is used there is very

seldom any subsequent soreness. When it is not used and there is subsequent soreness, I believe it is due to irritation at the periapical region, caused in a large number of these cases by the medicament itself. Cases arising from this cause would seem to show that the use of eugenol was indicated.

When eugenol is used and a subsequent soreness develops, I believe it can be rationally explained, as follows: The precipitation which follows the addition of solution No. 2 and eugenol to solution No. 1 seals the apical foramina if they are small, and if they are large, the gutta-percha filling does it. This precipitation effectually sterilizes the

root-canal, and with the gutta-percha filling cuts off any subsequent reinfection from this source, but there is an apical infection existing which has not yet been dealt with, and nature has to clear up this infected region.

The vent for gas or pus has been sealed, and unless these can be absorbed as fast as they are formed, soreness is sure to develop. If this kind of trouble arises and pus forms, do not ream out the root-canal. A lancet-thrust will give relief, and the case will clear up of itself. Careful technique is as necessary with this method as with any other successful one.

139 NEWBURY ST.

REVIEW OF CURRENT DENTAL LITERATURE

[*International Abstract of Surgery*, Chicago, August 1918. (*Supplementary to Surgery, Gynecology, and Obstetrics.*)]

War Injuries of the Face and Jaws: Collective Review. BY ROBERT H. IVY.

This review is a collation of ninety-three articles which have been selected with rare judgment from the enormous mass of literature on war surgery of the face and jaws, in American, British, French, Italian, Swiss, and German journals. The work has been done with painstaking elaborateness, accuracy, and detail. The experiences and views of seventy authors have been intelligently condensed and synthesized into the harmonious entity which Ivy herewith presents to us. This concise and authoritative summary should be studied at first hand by every dentist expecting to enter military service. The bibliography, which we append *in toto* from the original, is the most complete and important working index on this subject which has yet appeared.

In the field of facial surgery the first prin-

ciple to stand out is the importance of the close association of the surgeon with the dentist in the treatment of these cases, which attract particular attention by reason of the disfigurement which they cause. The second principle is that a definite plan of treatment should be initiated at the earliest possible moment after the receipt of the injury.

Mandibular fractures are classified according to the seat of the lesion (symphysis, body, ascending ramus, condyloid and coronoid processes), and also according to whether or not there is loss of substance. Under the plan of early special treatment the fractures are easily reduced, permitting the insertion of a fixation appliance with the teeth in normal occlusion (30). Several forms of temporary splints have been devised (74). Following this, at the earliest possible moment, full access is surgically secured to the fracture with the purpose of limiting hemorrhage, sepsis and necrosis, and obtaining a limited and relatively aseptic scar. This is an indispensable preliminary to a systematic ap-

plication of bone surgery (89, and, in part, 90). In this primary operation it is particularly essential that no loose fragments of bone be removed from the site of the fracture, as in many cases pieces of bone apparently hopelessly injured will recover their vitality and serve as a valuable matrix for repair (51).

When the time comes for definitive fixation, if reduction is resisted by scar tissue or callus, surgical division of the soft tissue or callus is indicated, followed by immediate fixation of the fragments in correct position. The form of fixation to be applied depends upon the location of the fracture, the amount of substance lost, the amount of displacement, the number, condition, and position of the teeth present. Among the most instructive papers bearing on this question are Nos. 12, 28, 36, 38, 41, 42, 50, 51, 81, 84, and 82.

The majority of gunshot fractures of the mandible involve the body of the bone anterior to the last existing tooth, and are characterized by considerable displacement and loss of substance. Two schools of practice may be recognized in the handling of cases with loss of substance: (a) that which considers that consolidation of the fracture should be assured by drawing together the ends of the bone even at the sacrifice of the normal occlusion of the teeth (89, 49, 12), and (b) a group to which the majority of workers belong who believe that the re-establishment of the normal occlusion of the teeth is the primary consideration. For this latter group, the best method of maintaining separation and of fixing the fragments in their normal position in relation to the upper teeth in the majority of cases of gunshot fractures of the mandible, is by the metal band and wire splint, consisting of a stout wire spanning the gap, attached by crowns or bands to sound teeth on each side (50 and 51). For fractures of the upper jaw there is employed a modified Kingsley bar splint, attached with straps to the vertex of the skull.

The complications of gunshot wounds of the face and jaws are hemorrhage (90, 53), pneumonia (51, 90), grave local and general sepsis (90), trismus (47, 57), pseudo-arthritis, facial paralysis (67), and salivary fistulae (68, 15, 76, 14).

Where hemorrhage is persistent and resists local measures, ligation of the individual

artery supplying the part is resorted to. Broadly speaking, (a) bleeding from the floor of the mouth comes from one or both lingual arteries or their branches: (b) from between the fragments of a broken mandible, arises from the inferior dental: (c) from the cheek or lip, has its origin in a branch of the facial: from the pharyngeal and tonsillar regions, will call for ligation of the external carotid. If it be impossible to determine the individual artery involved, or if the case be particularly urgent, the external carotid may be ligated high up so as to avoid thrombosis and embolism in the common carotid.

Infections of the respiratory tract (bronchitis and broncho-pneumonia) are often induced in septic mouth cases by the use of general anesthesia (51, 90). Consequently local anesthetics should always be employed wherever possible. Since the completion of Ivy's summary, there have appeared two papers which have for their particular purpose the elimination of these dangerous bronchial and pulmonary sequelae to general anesthesia (Wade and Rockey, *DENTAL COSMOS*, October 1918, p. 942).

Where the trismus or constriction (47, 40, 12, 44, 90, 57) is due to bony ankylosis, surgical interference is necessary; but where it is due to cicatricial bands of connective tissue or to pertinacious and high grade contraction of the muscles of mastication, it may be relieved by spreading the jaws apart by one or another of the many forms of mouth-openers which have been devised, with moderate but sustained pressure, or by forcible stretching under anesthesia, and after-treatment with screw gags.

The indications, technique, and results of bone or cartilage transplantation in pseudo-arthritis have been given the close attention of many workers (48, 59, 19, 81, 32, 46, 8, 64, 65, 66, 62, 63, 85). Ivy has carefully analyzed this literature. Bone-grafts are indicated, according to practically all authors, only in old cases of pseudo-arthritis. Aside from cases with great loss of substance, the bone-grafting operation should always have been preceded by a prolonged treatment by prosthetic fixation whose inefficiency should have been well demonstrated. The essential requirements emphasized by practically everyone for successful grafting are as follows:

(a) Operation should be performed only in the absence of any inflammatory or pathological condition in the region; (b) communication of the mouth cavity with the wound must be avoided; (c) it is indispensable that as perfect immobilization as possible be assured by apparatus fixing the lower teeth to the upper.

But a single case of facial paralysis due to gunshot injury is described (67). This was treated by muscle anastomosis. This operation, while far from restoring function, nevertheless caused to a large extent the disappearance of the asymmetry of the face when the muscles are at rest.

For salivary fistulae, the simple method of immobilization of the jaws (76), while not infallible, is always worthy of trial. Other methods of treatment (14 and 15) have already been referred to in the DENTAL COSMOS (Dieulafe and Deupès, April 1918, p. 352).

The question of feeding is a highly important one (81, 12, 51). Not only must the diet be nutritious to insure a maintenance of or even a gain in bodily vigor, but it must be as varied as possible and presented in an inviting form to uphold the personal morale of the patient. The character of the diet will, of course, be determined by the general state. It must, at first at least, be wholly liquid, and hence administered in large amounts at relatively frequent intervals. If possible, the menus of two consecutive feedings should be decidedly different. There is no mention of a case where rectal feeding was necessary.

The cosmetic or esthetic phase of facial war surgery has not been neglected. That psychically this is of great importance to the patient has been signalized by A. von Wagner (*Oesterr. Zeitschrift f. Zahnheilkunde*, 1916, Jg. xiv, p. 201). "Beobachtungen ueber den Einfluss der Kiefer- und schweren Gesichtsverletzungen auf die Psyche").

Plastic repair of war injuries of the soft parts is brought about by the employment of various well-known methods used in civil practice, viz, by free Wolff and Thiersch grafts, by sliding flaps from neighboring parts, by pedicled flaps from near by or from distant parts (10, 24, 25, 33, 35, 43, 70, 60, 61, 77, 78, 79, and 90). Most of the authors insist on immediate replacement after injury of the lacerated tissues into their approximately correct position, thus enormously

facilitating later corrective measures. Secondary plastic operations should not be performed too early when infection is still present in the scar tissue. While waiting for the subsidence of infection, the time can be utilized for controlling and limiting contraction of the scar tissue as far as possible.

The operative treatment of the case of facial paralysis (67) mentioned in Ivy's abstract, in large part belongs to this consideration of cosmetic restorations. Also for this purpose, need may arise for resort to bone or cartilage transplantation (*q. v. supra*).

The general consensus of opinion favors local and regional anesthesia for the performance of secondary plastic operations on the face and jaws. The anesthetic of choice is novocain-adrenalin. For technique see 88 and 7. Where general anesthesia is to be used, it would be well to consider the advice and methods of Wade and Rokey (DENTAL COSMOS, October 1918, p. 942).

Prosthetic facial reconstruction requires on the one hand great artistic ability, and on the other, mechanical ingenuity. The replacement of lost features by painted copper masks is considered in article 93. A plastic material has been adapted for this purpose (78, 79, 80), which can be adjusted from time to time by the patient himself.

To summarize the five foregoing paragraphs, the cosmetic or esthetic phase of facial surgery involves a consideration of (1) plastic surgery of the soft parts, (2) bone and cartilage transplants, (3) muscle anastomoses (67), and (4) the employment of prosthetic appliances for facial reconstruction.

Measurement of the Force of the Jaws. BY PIERRE ROBIN.

The particular purpose of this study is to aid in the recognition of functional disabilities sequent to war wounds, and in the discovery of malingerers. It is obvious that the

patient cannot eat (1) if he lacks a certain number of teeth, (2) if his mouth cannot be sufficiently opened, and (3) if his masticatory mechanism lacks the sufficient muscular force. Robin's buccal dynamometer objectively records the degree to which the mouth can be opened, and the masticatory muscular force. The construction of the instrument is briefly described.

[*Colorado Medicine*, Denver, August 1918.]

Asepsis and Antisepsis in Modern Dentistry. BY S. W. SCHAEFER.

Modern dentistry as commonly practiced is partly still in the pre-Listerian period, partly in the antiseptic period, and only to a slight extent in the modern aseptic stage.

The greater aseptic technique that seems advisable may be considered under three heads: Care of hands, of instruments, and of towels, napkins, and dressings. As to the hands: Mere scrubbing of the hands with a handbrush is probably all that is necessary for the average dental work, unless the hands become infected with pathogenic material (pus, calculus, saliva, etc.), when in addition they should be soaked in alcohol or a solution of mercuric chlorid. In the filling of root-canals, Schaefer believes sterile rubber gloves will be those worn by the dentists who get the best results.

As to the instruments, they should be sterilized by boiling, and after boiling *should be kept sterile*. For this latter purpose sterile towels and dressings are a necessity. All towels that cover the operating stand, and

all cotton and gauze that goes into the patient's mouth, should be sterilized by steam. By having the operating stand covered with a sterile towel, the instruments after they have been boiled can be laid thereon without danger of becoming reinfected. After the operation the instruments should in every case be boiled before being replaced in the cabinet, so as to prevent any infection of the cabinet, and then should be boiled again immediately before use.

In the operating room there should be no dry dusting or sweeping. The handpiece should be wiped before each operation with a cloth wet with alcohol or a dilute phenol solution, or better still, be boiled in a soap solution.

Between cases, the part of the X-ray apparatus that it is necessary to touch in making adjustments should be cleaned with alcohol or a phenol solution.

[*Riforma Medica*, Naples, March 30, 1918.]

A Case of Noma Following Paratyphoid B. BY ENZO ROMANELLI.

The case was that of a boy of twelve years. On the fifth day of the paratyphoid fever, the oral symptoms began to manifest themselves. Clinically they were recognizable as noma, which was confirmed by the microscopic examination (spirochetes, micrococci, and fusiform bacilli). Bact. diphtheriticum could not be found. Arseno-benzol, for the noma, was injected and applied locally without benefit. Death resulted.

PERISCOPE

Malformations of Jaws and Teeth.—Robin (*Paris Medical*, June 1918) has found in many cases that some malformation of the jaw, of teeth, or cheek in children was responsible for inadequate mastication or inadequate intake of air. His illustrations and clinical histories confirm the importance of correction as the first step in causal treatment of disease in the stomach, bowel, or chest.—*Journ. A. M. A.*

Soldering Contact Points on Inlays and Crowns.—The quickest and easiest way is to heat in the flame until red and then cool in the air, which oxidizes the whole surface. Now by means of a toothpick (one of the very few uses a toothpick serves), place a smear of flux paste just over the area where the solder is to flow; place a piece of solder, and flow—it will not flow where there is no flux.—EARLE H. THOMAS, *Dental Review*.

Ionization.—In electric ionization the conducting wire, electrode holder, and active electrode should all be so light in weight that they may be easily supported by the tooth or root being treated. Make a light holder by running about an inch of ordinary copper bell-wire into the rolls to flatten it, and wind this thin, flat part in a spiral around the base end of an ordinary barbed broach. Let the base of all active electrodes be made to slip into this spiral spring holder. A barbed broach makes a splendid active electrode where the metal does not matter. This holds properly a very small amount of cotton at the tip, and also prevents the electrode from slipping out of the root-canal.—F. D. PRICE, *Oral Health*.

Idiosyncrasy to Dichloramin-T.—Soto relates that he applied dichloramin-T in a case of rebellious purulent ethmoiditis. He ordered the woman to use the dichloramin-T in a 0.5 per cent. dilution, in the form of a spray, morning and evening. The atomizer used was made entirely of glass, and she was instructed not to squeeze the bulb more than ten times at one application. By the fifth day of this treatment the nose, lip, and cheeks had become much swollen and blistered, as also the nasal mucosa. On suppression of the spray the whole subsided in a few days. Thinking that the preparation of the spray had been defective, he had a new supply prepared, but this caused the same disturbance as before, even more pronounced.—JL. A. M. A.

Importance of a Proper Contact Point.

—If there is any one spot about a filling of which it can be said "That is the most important part of the whole operation, the part upon which depends the success or failure of the whole work," that spot is the contact point. Its importance is like the keystone of an arch; unless present in its proper form all the surrounding work will fail. If the contact point is omitted the first evil to follow is the leaking of food into the space during mastication, causing great annoyance to the patient, and being a constant menace to the filling at its weakest point—the gingival margin. Or the teeth may work together, as they sometimes do, in which case there will be a contact surface extending all the way from the occlusal to the gingival, which would bring the margins of the filling in contact with the surface of the approximating tooth, and what could more surely invite recurrence of decay?—HORACE I. BEEMER, N. J. *Dental Journal*.

Blocking the Ophthalmic Branch of the Fifth Nerve.—The blocking of this branch is becoming of more interest to the dental surgeon at this time, owing to war injuries of the maxilla. The blocking of the maxillary branch in such cases would not prove adequate for complete anesthesia unless we included the ophthalmic branch. The same general technique that is used for the maxillary branch, with only two exceptions, can be followed. To avoid trouble with the internal maxillary artery, the injection should be slightly to the buccal. The depth of penetration should be from four to five centimeters, allowing the needle to hug the bone closely. Five cc. of a two per cent. solution of novocain will be sufficient for complete anesthesia.—F. W. FRAHM, *Pacific Dental Gazette*.

Wax Inlay Technique.—Use a wax that has a high melting-point; one that will not be disturbed by body temperature. Warm the wax in hot water so that it may be easily placed in position; chill, remove, carve, polish, and mount with a sprue wire attached at the contact point; now clean the surfaces of the inlay with acetone and a fine camel's-hair brush before investing. Be sure to use the proper amount of water and investment material necessary for a perfect mix. When mixing the investment material tap the mixing bowl repeatedly to dislodge all air-bubbles, pour the investment, and allow it to set for twenty-five minutes; then you can slowly burn the wax out of and anneal the investment. The casting can be done in either a hot or cold mold, using either 22- or 24-k. gold.—*American Dentist*.

Recurrent Dislocation of Lower Jaw.

Tying up the coronoid process or the tissues inserted on it to the zygoma is suggested by Blake (*Annals of Surgery*, August 1918) as an operation in these cases. This procedure is less difficult than any careful and accurate work on the joint itself, and further, it acts to a much greater mechanical advantage, in that the coronoid is 3 or 4 cm. in front of the joint, and is by so much in a better position to withstand trauma tending to dislocation. A case is cited in which this procedure was employed successfully. An incision was made along the lower border of the zygomatic arch, and the fibers of the masseter separated from it. This incision was well above Stenson's duct and parallel to the facial nerve fibers. With some difficulty the coronoid process was reached; it was much deeper than had been anticipated, and Blake was not able

to do what he had originally planned—this was to drill through the tip of the coronoid, thread a piece of silver wire through the hole, and lace this over the zygoma. He therefore looped the wire first over the zygoma and then brought it down and carried it through the insertion of the temporal muscle and the periosteum on the front of the coronoid. He twisted the ends together, flattened it, and closed the wound without drainage. The wire loop was long enough to allow the jaw to open for 2 cm. or 1 inch between the incisors. The masseter was carefully sutured to its origin; bandages held the jaw closed, and the wound healed by first intention. The jaw was immobilized three weeks. More than a year after the operation, the jaw is normal and reliable in every way, the excursion being about 4 cm. at the incisors.—*Journ. A. M. A.*

To Reduce Expansion and Contraction of Amalgam.—To reduce the expansion and contraction of an amalgam to the lowest possible point is largely a matter of mixing. The manufacturer may have made as nearly a balanced alloy as it is possible for him to produce, and yet the finished filling will fall far short of the possibilities of the alloy because of a careless use of mercury in the amalgamation, and also in the packing of this plastic material in the cavity. The operator should always weigh in an accurate balance both the mercury and alloy, allowing a very slight excess of mercury to secure a smooth mix and aid in packing. This excess should not be removed until the filling has been very thoroughly condensed by careful stepping with a suitable plugger, sufficiently large to prevent the inclosing of any air-spaces. The excess mercury should be removed with the portion of the mix remaining above that which was needed for the filling of the cavity.—F. W. FRAHM, *Pacific Dental Gazette*.

The Porcelain Inlay.—After all these years in the practice of porcelain, and being one of the few who have made a record that stands as a guide to a great many, the question suggests itself, "What have I found that has represented the most substantial feature leading toward success?" The answer is, depth of cavity and bulk of material. It is very gratifying to see cases after twenty to twenty-five years that are looking practically as well as the day they were inserted, and those cases were made at a time when simplicity of cavity formation was the first objective. At that time there was not any dis-

cussion about how a cavity should be formed, as there were few who knew anything about cavity formation. So we used a simple form, and today these few basal directions are not improved to any material extent.

Regarding the direct or indirect method, I stand here as an exponent of the direct method, as I have yet to see the indirect method used where there was not more tooth structure cut away than was necessary, and I have great reverence for the preservation of tooth structure. All the indirect methods I have seen have, as a rule, been rather ruthless, and excessive tooth-cutting has been resorted to.—W. A. CAPON, *Journ. N. D. A.*

The Caduceus and the Emblem of the Medical Profession.—The caduceus, the rod surmounted by the extended wings and entwined by the two serpents, though regularly used in that connection, is not especially the emblem of the medical profession. According to the Century Dictionary the caduceus is a symbol of peace and prosperity, and in modern times figures as a symbol of commerce. The rod or wand is supposed to be the wand of Mercury, the god of commerce. The rod represents power; the serpents represent wisdom, and the two wings, diligence and activity. As stated by Dr. Samuel P. Gerhard (*Journ. A. M. A.*, April 24, 1909), the true ancestral symbol of the healing art is the knotty rod and serpent of Esculapius, the device adopted for the emblem of the American Medical Association. The significance of this device is much the same as that ascribed to the caduceus, but as Dr. Gerhard has shown from history and mythology, the serpent as the representative of wisdom has been from time immemorial linked up with the healing art. Dr. Gerhard says:

Esculapius was always pictured with a knotty rod in his hand, the knots indicating the many difficult problems of physics to be solved in the treatment of the ailments of mankind. Therefore, applying these thoughts to the symbol, we have in the entwined serpent power, wisdom, and health, together with the protection and support against disease and the difficulties to be overcome by the knotty rod. With this historical symbol the sanctity of medicine can be pictured, and the doctor is shown in his true light, not only as a laboratory scientist and as a practitioner, but as a teacher and adviser to the patient, the family, and the community, in all the difficult problems that arise concerning health and disease.—*Journ. A. M. A.*

Preparedness League of American Dentists.

ORGANIZED UNDER THE AUSPICES OF THE N. D. A.

THE DENTAL COMMITTEE OF THE GENERAL MEDICAL BOARD, WHICH IS THE AGENCY FOR THE MEDICAL AND DENTAL PREPAREDNESS IN THIS WAR EMERGENCY, HAS MADE IT POSSIBLE FOR EVERY DENTIST IN THE UNITED STATES TO ASSIST IN THE WORK, UNDER THE SUPERVISION OF THE PREPAREDNESS LEAGUE OF AMERICAN DENTISTS.
HEADQUARTERS AT 50 EAST 42D ST., NEW YORK, N. Y.

Preparedness League Notes and News.

By R. OTTOLENGUI, *Publicity Committee.*

FROM THE PRESIDENT.

OUR Director-general is planning to give, through the members of the League, free dental service to such families of soldiers, sailors, and marines as shall be found worthy by the Home Service department of the Red Cross.

This is a most commendable activity of the League, and should be supported by its entire membership. Only necessary service will be rendered, with special reference to children and expectant mothers, who will doubtless make up the greater percentage of cases requiring treatment.

It is possible that some members of the League may not be in full accord with this plan, but to such I would say that we have thus far undertaken no more necessary nor worthy activity. Suppose that you were in the trenches more than three thousand miles away from your wife and your children, who were left without sufficient support, suffering far more than yourself, in patience and silence. Would you not be cheered and thankful to know that skilled dentists stand ready to give them the best service within your power? Would it not fill your heart with thanksgiving, and make your cross easier to bear?

Then, for the sake of your conscience, your love of your own flesh and blood, do not advance a single argument against this great work, but add it to your already overburdened duties, and the blessings of real sacrifice will be yours throughout your lifetime. It is far better to sacrifice than to regret. Now is the time when every ounce of skilled energy must be utilized to the glory of our flag, our profession, and humanity. All true Americans are learning to give and to sacrifice, and surely no more worthy objects can be found than the wives and children of the men who are making the supreme sacrifice

that our beloved country may remain clean and fit for the living as well as for the myriads yet to be born.

THE RED CROSS AND THE DENTAL MOTOR CAR.

The Red Cross will accept and ship to France all dental motor cars turned over to the Government by the League, and promises that they will be used for care of the soldiers only. With this assurance the League is ready to begin active work in supplying them as rapidly as possible.

Members of the dental corps in France are anxiously awaiting their arrival, and we have many letters urging us to get the cars over there, as there is the greatest need for them. Commanding officers have promised co-operation, and it is now up to the League to supply the demand. Fifteen cars have been completed, some of which were ordered by the Italian Government for child welfare service. No development has created greater interest in our profession, especially by the public, than our dental motor car.

Let every organized body of dentists plan immediately to raise money for this purpose, and I suggest that the officers write Dr. S. Marshall Weaver, Chairman, 620 Rose Bldg., Cleveland, Ohio, for full instructions.

This matter is vital, therefore urgent.

OUR INSTRUCTION COURSE.

Conditions generally in the educational department of our profession have been so unsettled while undergoing the changes subsequent upon militarizing dental institutions that those in charge of arranging a course of instruction in war oral and dental surgery have been unable to make definite arrangements in this most essential matter.

In the meantime, data are being compiled,

plans formulated, and co-operation of instructors gained, so that when the word is given to proceed we will be ready for action. The situation has worried your President greatly, as he has endeavored to establish a reputation for the League of accomplishing every good object undertaken, and it is no idle assurance to say that we are on the job to see this object a big success.

RECLAIM.

Colonel Logan asks all League members to reclaim men dentally defective and put them in class 1 A. We will back him up in this, and do our bit to make an army of five millions. *The war is not yet won.*

J. W. BEACH, *President.*

AMERICAN RED CROSS DENTAL AMBULANCES.

AND now they are utilizing dental ambulances in France, that American soldiers may have healthy mouths, with consequent good digestion and health. The first two of these dental ambulances on record were equipped through the efforts of Mrs. William Boyce Thompson, and given through the American Red Cross to the dental department of the United States Army.

These ambulances have all the appurtenances of the modern dental office, with the added advantage of being able to visit the patient in all sorts of out-of-the-way places. They consist of a main operating room and two good-sized tents. Every contrivance approved by the dental profession is installed in the ambulance.

In the center room, or office proper, is a complete dental outfit, with separate bracket for instruments, electric engine, fountain cuspidor, pressure tank with syringe and sprays, hot and cold water faucets, steam sterilizer, filter, vulcanizer, electric lathe, blow-pipe, nitrous oxid and oxygen apparatus, sanitary cabinet for instruments, a full set of forceps, and duplicate sets of instruments. There is even a typewriter for office record use.

The car is lighted by electricity generated by batteries especially built for the ambulance. Should they fail, provision is made for acetylene gas lighting.

When the car is in transit a field outfit, which closes up in three containers, is stored in the office. This is set up as soon as the car is ready for service. On either side of the office is a tent, one used for the field

outfit; the other is converted into sleeping quarters, or it may be used as an adjunct operating room.

While dental treatment is being given in the office, one of the tents may be used for the more difficult operations. The car is manned by a crew of two officers, two dental assistants, and a chauffeur. In hot weather the sides of the tent may be rolled up, insuring all possible ventilation.

One of these ambulances is in active service at Camp Upton, the other at Camp Greenleaf. In all camps, newly arrived draftees carry with them trifling ailments—measles, mumps, and the like. The men are quarantined and as they cannot go to the dentist, the dental office honks up to them.

Camp Meade also has a dental ambulance, the gift of the Cleveland Unit of the Preparedness League. The Connecticut Unit provided funds for another which is going to France to serve our boys at the front. The Red Cross has thirteen of the dental ambulances, either completed or in process of construction. Three of them are for service in France and the other ten (three dental ambulances and seven baby-saving trucks) are on their way to Italy. All thirteen will go "over there." The Red Cross considers that the work among the babies and children of the war-swept lands will do much to rehabilitate future generations.

In order to continue this work and to provide for the greatly increased number of men who are being sent overseas monthly, the Red Cross will need the united support of the American people, that its mission of mercy and humanity may not be halted. For that reason the Red Cross will hold its second annual Christmas roll-call during the week of December 16th to 23d, when, it is hoped, every American man, woman, and child will place his or her name upon the Red Cross roster. Last year 22,000,000 adults and 8,000,000 children responded to the call, and took a nation-wide pledge to stand squarely behind the flag in our war for justice and liberty for all.

The above paragraphs, under the heading, "American Red Cross Dental Ambulances" is matter which has been received direct from the publicity bureau of the Eastern department of the Red Cross. It is therefore authentic. All League officers are requested to have this published in their local newspapers during the next Red Cross drive, which will begin December 16th.

ARMY AND NAVY DENTAL NEWS

Examination for Army Dentists.

AN examination will be held throughout the country on November 4th for appointment to the army dental corps. Approximately seventy vacancies are to be filled. An examination of privates of the army who are graduate dentists will be held within the next thirty to ninety days. Some of these men are already in the dental corps, but many of them are performing regular military duty in the various arms of the service. Their names have been assembled from the registration cards of the national army, and it is estimated that about four hundred in all are eligible to take this examination. These men will be given the first opportunity to fill vacancies, and those members of the former dental reserve corps, now in an inactive status, will be called to active duty as needed, probably after January 1st. Under the orders now in force, no men are issued commissions except as vacancies occur and their services are needed.—*Army and Navy Register*.

Naval Dental Corps.

On November 11th will be held an examination of candidates for appointment to the regular dental corps of the navy. This examination, which will be held simultaneously at Washington, at Great Lakes, Ill., and Mare Island, Cal., is for the purpose of filling fifty-six vacancies, and will be open to dentists between twenty-one and thirty-two years of age, provided they are not in class 1 of the draft; only men in deferred classifications will be considered. On October 14th an examination will be held for promotion of dental officers, and also for the appointment of those who have been in a probationary status. As a result of this examination, it will be possible to advance thirty dental surgeons to the grade of lieutenant, twenty-eight of whom may be promoted to the temporary grade of lieutenant-commander. This examination will be competitive, since the candidates are now serving a probationary period, and have no seniority. After qualifying in the forthcoming examination they will be assigned a place in the register. A training school for the naval dental corps has been

established at the training station, Great Lakes, Ill., with Lieut.-commander Anson F. McCreary, dental corps, in charge, for the benefit of young officers of that corps. The course will comprise both military training and professional instruction. The course, for the present at least, will be open only to those who have been commissioned. The old dental reserve corps passed out of existence with the appropriation action of July 1st, and was superseded by the dental reserve force, members of the former corps having been required to enroll in the reserve force before being assigned to active duty. The age limit in the dental reserve is twenty-one to forty-nine.—*Army and Navy Register*.

Surgeon-general Merritte W. Ireland.

ON October 3d the President sent to the Senate the following nomination: "To be Surgeon-general with the rank of Major-general: Major-General Merritte W. Ireland, M.C., U. S. Army." It may be taken for granted that this nomination will be confirmed by the Senate. The appointment of General Ireland to this position will give general satisfaction to the Medical department of the army. The record of General Ireland in the department is a record of thorough, conscientious service, fitting him particularly for the position which he now is to occupy.

General Ireland was born at Columbia City, Ind., May 31, 1867. He was graduated from the Detroit College of Medicine in 1890, and later, in 1891, was graduated from Jefferson Medical College, Philadelphia, immediately afterward entering the service as first lieutenant and assistant surgeon. He began his military career at Jefferson Barracks, Mo., on May 27, 1891. In 1902 he entered the Surgeon-general's office, working under Surgeon-general O'Reilly and continuing under Surgeon-general Torney. He was promoted to major and surgeon, and to major, M.C., August 3, 1903, and to lieutenant-colonel May 1, 1911. He left the office of the Surgeon-general in 1912, again going to the Philippines, where he was stationed as post surgeon at Fort William McKinley. He thus had a

continuous service in the Surgeon-general's office of approximately ten years. He returned to the United States and was placed in charge of the base hospital at Fort Sam Houston in 1916, and accompanied General Pershing to Mexico as surgeon of the American Expeditionary Forces to Mexico. When the United States entered the great war he accompanied General Pershing to France as chief surgeon of the American Expeditionary Forces, was promoted to the rank of brigadier-general, May 1, 1918, and more recently to the rank of major-general and surgeon-general of the expeditionary forces.

Our new surgeon-general has filled practically every position to which the men who will serve under him may be called—surgeon of volunteers, post surgeon, assistant in the Surgeon-general's office, supply depot, surgeon-general of the expeditionary forces—a complete record which indicates that the chief will know what confronts each of his subordinates.—*Journ. A. M. A.*

Inquiry Relative to Army Dental Corps.

REPRESENTATIVE McKeown proposes in H. Res. 430, that the Secretary of War report to the House of Representatives the number of dentists commissioned in the dental corps of the army to September 1, 1918, together with the number of dentists who are members of the National Dental Association to whom commissions have been issued, together with the number of dentists who are non-members of any association to whom commissions have been granted, and are in the active service.—*Army and Navy Register.*

Promotions.

ARMY DENTAL CORPS.

THE following appointments (promotions) are announced (September 21st):

To be CAPTAINS—for existing emergency: 1st Lieuts. Roy H. Kernohan, Harry L. Westney, Wm. H. Delbridge, James W. Simpson, James B. Eastman, Archibald R. Lucas, George A. Bullard, Edmund U. Potter, Page P. A. Chesser, Harold M. Whitney, and Henry H. Thacker.

Announced September 28th:

To be CAPTAINS—for existing emergency: 1st Lieuts. Lawrence K. Anderson, Leslie D. Baskin, Charles H. Brammell, George Krakow, Harry E. Smalley, Francis M. Tench, Richard K. Thompson, Wm. C. Webb, Jr., Theodore D. Grannick, Julius Seamans, Arthur T. MacMillan, and Clark J. Hollister.

Announced October 6th:

To be LIEUT.-COLS.: John A. McAllister, Jr., George H. Casaday and Julien R. Bernheim.

To be MAJORS: Mortimer Sanderson (deceased), John H. Snapp, Wm. A. Squires, Arnett P. Matthews, John W. Scovel, and Charles DeW. Deyton.

To be MAJOR—for existing emergency: Capt. Clinton C. Messner.

To be CAPTAINS—1st Lieuts. Millard F. Stenbridge, Angus M. Sellers, Theodore J. Richardson, Alva L. Cowart, Richard F. Doran, Frederick L. Litty, Jonas H. Stewart, Roy D. Smiley, Rozelle M. Cope, Louis T. Austin, Hugh D. Conlon, Wm. A. Duffy, Nelson T. Shields, Jr., Ernest P. Shaw, Walter B. Reeves, James M. Ackley, Roy White, LeRoy D. Shafer, and Charles Van B. Beard.

Announced October 12th:

To be MAJOR—for existing emergency: 1st Lieut. Reuel May.

To be CAPTAINS—for existing emergency: 1st Lieuts. Rudolphe T. Turcotte, Emil L. Aison, Joseph A. Ahern, Victor A. Vores, Robert J. Steedman, Theodore C. Swendsen, Clarence S. Lister, John H. Malony, Moses C. Beal, Hurst V. Boyd, Matthew F. Carney, Lawrence T. DeVine, Dudley C. Hughes, O'Gorman J. Lane, Willis R. McCorsberry, Edward L. Masten, Frank W. Meeske, Joseph F. Mulcahy, Elmer E. Purington, Harry E. Rice, Francis P. Riggs, Arthur C. Webb, Herman R. Moore, Walter W. Gochenour, and Robert E. Giddens.

Assignments.

ARMY DENTAL CORPS.

Week ending September 21st.

Col. Wm. H. Chambers from duty at general hospital 6, Fort McPherson, Ga., to Charleston, S. C., for duty as department dental surgeon.

Week ending October 5th.

The following from duty in Hawaiian Department to San Francisco, Cal., for orders: Majs. Harry M. Deiber, Walter L. Reesman, Oscar G. Skelton, and Emmett P. Varvel.

The following from duty in Philippine Department to San Francisco, Cal., for orders: Majs. Eugene Milburn, Don G. Moore, Harry C. Peavey, Charles Taintor, Robert B. Tobias, and Lowell B. Wright.

Week ending October 12th.

Lieut.-col. George I. Gunckel to report to retiring board at Washington for examination.

SPECIAL NOTICE.

PLATINUM — IRIIDIUM — PALLADIUM.

GOVERNMENT REGULATIONS "LIMITING THE SALE, POSSESSION, AND USE OF THESE METALS AND COMPOUNDS THEREOF."

WE have been requested by the War Industries Board (Platinum Section) to give publicity to the official form of certificate required from all (dentists) purchasers of "Platinum, Iridium, and Palladium or compounds thereof" by dealers operating under License Form 10x, issued by the Director of Mines, through the War Industries Board, which limits the purchase, possession, and sale of dental supplies containing these metals. The form follows:

particularly to users of and dealers in dental supplies containing these metals.

Regulations.

SECTION 1. The War Industries Board is hereby designated, under section 21 of the Act of October 6, 1917, and the President's proclamation of October 26, 1917, as the agent of the Director of the Bureau of Mines in the execution of the regulations as hereinafter indicated.

SEC. III. From and after the date of these regulations, under the penalties prescribed by

Platinum Certificate.

To..... (*Dealer's name*).

I, the undersigned, hereby certify that I do not possess one ounce troy, or more, of unmanufactured Platinum, Iridium, or Palladium, or compounds thereof (including crude, scrap, filings, polishings, or sweeps), and will not possess dental supplies (excepting artificial teeth) containing Platinum, Iridium, and Palladium, or compounds thereof, in excess of my known requirements for thirty days.

[SIGNED]..... (*Purchaser*).

Date.....

The following extracts from the Rules and Regulations under the Act of Congress of October 6, 1917 (40 Stat. 385) as amended by the Act of July 1, 1918 (Pub. 181) limiting the sale, possession, and use of Platinum, Iridium, and Palladium, and compounds thereof, apply

section 19 of the Act of October 6, 1917, no person shall without a license—

Par. a: Purchase, sell, barter, or deal in unmanufactured platinum, iridium, or palladium, or compounds thereof (including crude, scrap, filings, polishings, or sweeps), except that sales may be made without a license to an authorized agent of the United States or

to a licensee authorized to purchase the same; or possess for more than 90 days after the date of these regulations one ounce troy, or more, of such unmanufactured platinum, iridium, palladium, or compounds thereof.

Par. b: Possess, use, sell, purchase, or barter, for purposes connected with his business, platinum, iridium, palladium, or compounds thereof (except that sales may be made without license to an authorized agent of the United States, or to a licensee authorized to purchase the same), if such persons be engaged in—

No. 10: Manufacturing and/or distributing dental supplies containing platinum, iridium, or palladium, or compounds thereof.

SEC. IV. Application for licenses shall be made under oath to any licensing agent duly authorized under the Act of October 6, 1917, as provided in the regulations issued under this Act.

SEC. V. Every applicant for a license will be required to submit with his application a sworn inventory of all platinum, iridium, or palladium, or compounds thereof, in his possession or control; and every licensee will be required to submit at such times as may be designated by the War Industries Board a sworn inventory of his holdings of platinum, iridium, or palladium, or compounds thereof, in whatever form they may be.

The Director of the Bureau of Mines, at the request of the War Industries Board, may at any time require from any user or possessor a detailed sworn inventory of any and all materials held by him containing platinum, iridium, palladium, or compounds thereof, and such inventory must be furnished promptly upon receipt of such requirement.

SEC. VI. All licenses shall be issued in the name of the Director of the Bureau of Mines and countersigned and delivered by the War Industries Board, and shall be and remain subject to the following conditions:

Par. a: Each license shall contain such appropriate conditions as the Bureau of Mines, through the War Industries Board, may impose.

Par. b: The Bureau of Mines through the War Industries Board may change the conditions of the license from time to time, as it may deem necessary.

Par. c: Records shall be kept by each licensee of all his sales, purchases, and other transfers of platinum, iridium, or palladium, or compounds thereof, and of articles containing platinum, iridium, or palladium, or compounds thereof, with the names and ad-

dresses of the purchasers, sellers and/or transferees, and the quantities involved, which records shall be open at all reasonable times to the duly authorized representative of the Director of the Bureau of Mines.

Par. d: Any and all platinum, iridium, or palladium, or compounds thereof, acquired under the authority of such license, shall be used strictly for the purposes and in the manner stated in such license.

Par. e: Upon request of the War Industries Board, the licensee shall report the prices at which sales of his products containing platinum, iridium, or palladium, or compounds thereof, are being made, and the right to prohibit further sale of such articles at prices deemed exorbitant by it is reserved to the War Industries Board.

SEC. VII. Any licenses issued hereunder may be revoked for violation of any of these regulations, or for violation of any of the conditions contained in such license, or if such revocation is deemed necessary or advisable for purposes of the national security and common defense.

SEC. VIII. The War Industries Board will, upon request, furnish a list of Government agents or licensees authorized to purchase platinum, iridium, or palladium, or compounds thereof. Neither the United States nor its representatives will assume any responsibility, financial or otherwise, where sales are made to licensees.

SEC. IX. The prices at which platinum, iridium, or palladium will be purchased by a duly authorized agent of the United States, or by such licensee as may be authorized to purchase or sell platinum, iridium, or palladium, or compounds thereof, will be such prices as may be determined by the proper governmental agency authorized to determine such prices.

SEC. X. Whenever such Government agents and such licensees as may be authorized to purchase platinum, iridium, or palladium, or compounds thereof, shall refuse to purchase the same from any person who is compelled by these regulations to sell the same, or is forbidden by these regulations to possess or use the same, then such person shall promptly notify the Platinum Section, War Industries Board, Washington, D. C.

SEC. XI. These regulations shall not operate to relieve any person upon whom an order requisitioning platinum, iridium, or palladium, or compounds thereof, may have been or may hereafter be served, from any obligation imposed upon him by such order.

Penalty.

SECTION 19 OF THE ACT OF OCTOBER 6, 1917:

That any person violating any of the provisions of this Act, or any rules or regulations made thereunder, shall be guilty of a misdemeanor, and shall be punished by a fine of not more than \$5000 or by imprisonment for not more than one year, or by both such fine and imprisonment.

License Classifications

AFFECTING DEALERS IN OR USERS OF DENTAL SUPPLIES CONTAINING PLATINUM, IRIIDIUM, AND PALLADIUM, AND/OR COMPOUNDS THEREOF.

No. 4: To purchase in any form which requires refining or smelting, and to possess for a reasonable time, the platinum, iridium, and palladium produced as a primary product or as a by-product of the smelting or refining. (See Section III, par. a, of Rules and Regulations regarding sale.)

No. 10-x: To purchase and possess and to sell to dentists (upon their certification that they will not possess more than a 30-day requirement, excepting artificial teeth), dental supplies containing platinum, iridium, and palladium, and/or compounds thereof.

(a) To purchase and possess in an amount equivalent to their known 30-day requirements, and to sell to dentists (upon their cer-

tification that they will not possess more than a 30-day requirement, excepting artificial teeth) dental supplies containing platinum, iridium, and palladium, and/or compounds thereof.

(b) To purchase and possess in an amount equivalent to their known 60-day requirements and to sell to dentists (upon their certification that they will not possess more than a 60-day requirement, excepting artificial teeth) dental supplies containing platinum, iridium, and palladium, and/or compounds thereof.

(c) To purchase and possess in an amount equivalent to their known 90-day requirements and to sell to dentists (upon their certification that they will not possess more than a 90-day requirement, excepting artificial teeth) dental supplies containing platinum, iridium, and palladium, and/or compounds thereof.

No. 13: To purchase and possess scrap, filings, polishings, and sweeps containing platinum, iridium, or palladium for re-sale to the United States Government or to licensees authorized to purchase same.

All communications regarding applications, licenses, inventories, or other matters pertaining to these regulations should be addressed to

PLATINUM SECTION

WAR INDUSTRIES BOARD

WASHINGTON, D. C.

SOCIETY NOTES AND ANNOUNCEMENTS

Dental Protective Association.

THE annual meeting of the Dental Protective Association of the United States will be held at the Palmer House, State and Monroe sts., Chicago, on December 16th, at 4 P.M. Reports of officers will be presented, a board of directors elected, and such other business transacted as should come before the association. All members are urgently requested to be present.

J. G. REID, *President.*

J. P. BUCKLEY, *V.-pres. and Sec'y.*

D. M. GALLIE, *Treasurer.*

Ohio State Dental Society.

THE fifty-third annual meeting of the Ohio State Dental Society will be held in the Memorial Hall, Columbus, December 3, 4, and 5, 1918.

An excellent program of papers and clinics is assured, with some new features of special interest.

A cordial invitation is extended to members in good standing of other state societies to meet with us.

F. R. CHAPMAN, *Sec'y,*

305 Schultz Bldg., Columbus, Ohio.

Michigan Board of Examiners.

THE next meeting of the Michigan State Board of Dental Examiners will be held at the Dental College, University of Michigan, Ann Arbor, Mich., November 18 to 23, 1918, inclusive. Applications and other information may be obtained by addressing

B. S. SUTHERLAND, *Sec'y*,
Owosso, Mich.

Rhode Island Board of Registration.

THE semi-annual meeting of the Rhode Island Board of Registration in Dentistry, for the examination of candidates, will be held at the State-house, Providence, R. I., December 3, 4, and 5, 1918.

Applications with fee must be in the hands of the secretary one week previous.

For further information address

ERNEST A. CHARBONNEL, *Sec'y*,
139 Mathewson st., Providence, R. I.

Pennsylvania Board of Examiners.

THE next examination of the Pennsylvania Board of Dental Examiners will be held in Philadelphia and Pittsburgh, on Tuesday, Wednesday, Thursday, and Friday, December 3, 4, 5, and 6, 1918, at Musical Fund Hall in Philadelphia and the University of Pittsburgh, Pittsburgh. The practical examination will be held on Friday, December 6th, the last day. Application papers can be secured from the department of Public Instruction, Harrisburg.

For further information address

ALEXANDER H. REYNOLDS,
4630 Chester ave., Philadelphia, Pa.

New Jersey Board of Registration.

THE State Board of Registration and Examination in Dentistry of New Jersey will hold their annual meeting and examination in the Assembly chamber, at the State-house, Trenton, N. J., on December 2, 3, 4, 5, and 6, 1918. License fee, \$25; re-examination fee, \$10. Practical tests required: Insertion of an approximal gold filling, with approximating tooth in position, compound approximal amalgam filling, a silicate filling, practical test of the applicant's ability in oral prophylaxis, and preparation of a cavity for an inlay with wax pattern. Also the solder-

ing of a bridge consisting of three or more teeth, exclusive of abutments, and one Richmond crown, which may be one of the abutments of the bridge; these must be made of gold or silver. The bridge must be struck from dies made from an impression of the mouth, and the articulating model, with the bridge, when soldered, must be submitted for inspection. An anatomical articulation of a full upper and lower set of teeth will also be required; teeth to be furnished by applicant. Wax bite properly trimmed and in place on models for inspection before setting up teeth.

Attention is directed to the following quotation from the dental law of New Jersey: "Applicant shall present to said board a certificate from the Commissioner of Education of this state, showing that before entering a dental college he or she had obtained an academic education consisting of a four-year course of study in an approved public or private high school, or the equivalent thereof." In accordance with this law the secretary will issue application blanks only upon presentation of the required certificate from the Commissioner of Education, State-house, Trenton, N. J.

Note.—Dental Radiography will be added to the list of theoretical examinations in June 1919.

Applications must be filed complete ten days before the date of the examinations. Address all communications for further particulars to

JOHN C. FORSYTH, *Sec'y*,
430 E. State st., Trenton, N. J.

Washington Board of Examiners.

THE next meeting of the Washington State Board of Dental Examiners will be held in Spokane, Wash., November 20 to 25, 1918.

FRANK B. LYNOTT, *Sec'y*,
Spokane, Wash.

Montana Board of Examiners.

OWING to the present war conditions and the lack of a sufficient number of applicants, the Montana Board of Dental Examiners will *not* hold the usual January examinations. The next examinations will be held at Helena, Mont., on July 14, 15, 16, and 17, 1919.

T. M. HAMPTON, *Sec'y*,
Helena, Mont.

Oklahoma Board of Examiners.

THE Oklahoma Board of Dental Examiners will hold their next regular semi-annual meeting at the State Capitol building, Oklahoma City, Okla., beginning December 9, 1918. Reciprocity only with Kansas, Missouri, Arkansas, Nebraska, Indiana, and District of Columbia.

For further information address

H. OVERBEY, *Sec'y*,
Ryan, Okla.

California Board of Examiners.

THE next meeting of the Board of Dental Examiners for the purpose of examining applicants for a license to practice dentistry in the State of California will be held in the City of San Francisco at the Dental College, University of California, beginning on December 9, 1918. All applications for examination must be filed with the board on December 9th at 9 A.M. Each application must be accompanied by (1) the fee of \$25; (2) diploma and license from other states; (3) diploma from an accredited high school giving a four-year course of instruction or a certificate signed by a state superintendent of public instruction (or similar officer) to the effect that such applicant has had scholastic preparation in all respects equivalent to that demanded for graduation from an accredited high school giving a four-year course of instruction, in the state from which such certificate is issued; in lieu of such

high-school diploma or certificate, an applicant who has been licensed in some other state of the United States for a period of at least five years may file his state license; (4) a testimonial of good moral character; (5) a recent unmounted photograph.

By order of the Board of Dental Examiners of California.

C. A. HERRICK, *Sec'y*,
133 Geary st., San Francisco, Cal.

Connecticut Dental Commission.

THE Dental Commissioners of Connecticut will meet at Hartford, November 21, 22, and 23, 1918, to examine applicants for license to practice dentistry, to examine dental hygienists for license to practice, and to transact any other business proper to come before them.

For blanks and further information, address

EDWARD EBERLE, *Recorder*,
902 Main st., Hartford, Conn.

Maryland Board of Examiners.

THE Maryland State Board of Dental Examiners will meet for examination of candidates for certificates on November 7 and 8, 1918, at the Baltimore College of Dental Surgery, Baltimore, Md., at 9 A.M.

For application blanks or further information apply to

F. F. DREW, *Sec'y*,
701 N. Howard st., Baltimore, Md.

THE DENTAL COSMOS

VOL. LX.

DECEMBER 1918.

No. 12

ORIGINAL COMMUNICATIONS

Sterilization of Root-canals.

By HERMANN PRINZ, D.D.S., M.D., Philadelphia, Pa.

From the Pharmacological Laboratory, Thomas W. Evans Museum and Dental Institute, University of Pennsylvania.

[SECOND PAPER.]

INTRODUCTION.

IN a previous paper (DENTAL COSMOS, April 1917) the writer presented certain experimental data concerning the various methods involved in the process of electro-sterilization of infected root-canals. This procedure, from a clinical viewpoint, has been eminently successful; it presented, as the Editor of the DENTAL COSMOS expressed it, "a method of root-canal sterilization based upon scientific and clinical investigation that apparently brings the question of root-canal sterilization within the sphere of mathematical precision."

At the outset the writer wishes to state that every word he has uttered about electro-sterilization of root-canals still holds good today, and that he does not retract one iota from his previous statements. The reader may be justified in

asking this question: Why, then, this apparent paradox in recommending a new method, if the first method was successful? The perusal of the following lines, it is to be hoped, will quickly convince the inquirer that the new method in its final analysis is merely a simplification of the original method as discussed in the first paper, *i.e.* the utilization of chlorin as a disinfecting agent for the purpose in view.

During electro-sterilization, chlorin is obtained by a process of ionization of a sodium chlorid solution which requires an expensive apparatus, a knowledge of physical chemistry not possessed by the average dental practitioner, and an expenditure of valuable time. Especially the latter item is of the utmost importance to the busy clinician. The proper utilization of time constitutes the most important economic factor in the exer-

cise of any calling. Hence when a method promises to assist in the curtailment of time expenditure while producing equally good results as another given method, it is deserving of earnest consideration by the clinical practitioner.

The agent which the writer here wishes to discuss, and which he employs for the purpose of furnishing available chlorin, is a new compound known as dichloramin-T. This compound was selected by Dr. H. D. Dakin for the purpose of sterilizing infected war wounds. The testing of its surgical value was entrusted to Dr. Walter E. Lee of the Pennsylvania Hospital of Philadelphia and Dr. Joshua E. Sweet, professor of surgical research, University of Pennsylvania (now in France). Captain Sweet was kind enough to entrust the testing of this preparation, in regard to its value in dental practice, to the writer, who is also under much obligation to Dr. Lee for data concerning the general surgical technique, literature, etc. Following Dr. Dakin's instructions, dichloramin-T and its solvents were first prepared by Dr. B. M. Hendrix of the department of physiologic chemistry, University of Pennsylvania. The writer is deeply indebted to these gentlemen for numerous courteous acts.

HISTORY.

From an historical point of view it is interesting to observe that chlorin in the form of its numerous preparations has had a rather checkered career within that group of substances generically referred to as disinfectants and antiseptics. In 1788, the French chemist Berthollet obtained a liquid which exhibited marked bleaching and disinfecting properties, and Tennant of Glasgow, in 1798, prepared a more stable compound in the form of chlorinated lime for similar purposes.

In 1792, the Javelle works, near Paris, prepared a liquid bleaching compound for commercial purposes by passing chlorin into potash solution, which since has become widely known as Eau de Javelle or Javelle water. Again, in 1820, Labarraque, a French pharmacist, modi-

fied this latter solution by substituting sodium carbonate for the potash salt. This solution, variously known as liqueur de Labarraque, as Labarraque's disinfectant fluid, or at present simply as Labarraque's solution, achieved great renown at the death of Louis XVIII, "for, thanks to the disinfecting and deodorizing values of his liqueur Labarraque was able to proceed with the embalming of the royal body, which was so profoundly decomposed that no one was able to approach it until after the application of the hypochlorite solution." (Dakin.)

When Semmelweiss, the assistant obstetrician of the Vienna lying-in hospital announced, in 1846, his epoch-making observation concerning the clinical causes of puerperal fever, he selected chlorinated lime solution as the agent *par excellence* for the destruction of that loathsome unknown "miasm" which was carried by the students, as he observed it, from the dissecting rooms to his wards, and which was the apparent cause of the scourge.

Again, during the civil war, chlorinated lime solutions were occasionally employed to check the frightful destruction of human life by hospital gangrene. However, principally on account of the caustic effect of the solutions employed, together with a faulty technique in its application, the compound never obtained the general usefulness which it rightly deserved. With the advent of modern bacteriology, chlorin has always been a favorite antiseptic in the hands of the experimental researcher, and within the province of the hygienist its application for the purification of drinking water and the sterilization of excreta it has achieved most remarkable results, and consequently it is at present very largely employed for such purposes.

Repeated attempts have been made in the past by bacteriologists to convince clinical surgeons and dentists that chlorin solutions are the acme of perfection as far as wound antiseptics are concerned. As a consequence, various preparations under more or less fanciful names have appeared on the market, among which Labarraque's solution, Ja-

velle water, electrozone, dental medietrina, radizin, antiformin, eusol, eupad, chlorazene, and many others are examples. All of these solutions show remarkable activities as far as their laboratory tests are concerned; nevertheless, in their practical application they do not produce the same satisfactory results, and hence they have proved disappointing to the clinician. It should be borne in mind that most of these preparations are strong irritants, and that chlorin solutions are rather labile compounds; all of the solutions named lose their activity within a week or two, hence the disappointing results when commercial stock preparations are employed.

PHARMACOLOGY OF DICHLORAMIN-T.

The halogens represent the most interesting and incidentally the most important group of those chemical substances which as a class are referred to as wound antiseptics and as general disinfectants. On account of their general behavior bromin and fluorin are of less importance for such purposes, while iodine and chlorin, because of their high efficiency and their universal adaptability from a clinical point of view, form the most important group among these substances.

At this moment chlorin is considered king among the chemical disinfectants; when freshly prepared, in the presence of moisture and a suitable temperature, it is the most active disinfectant known. From a technical point of view, however, numerous difficulties arise in its application which in the past have more or less interfered with its universal application. Chlorin as such is a gas which, while it may be readily compressed into a liquid, cannot be employed as such with any degree of satisfaction for wound treatment, as it is too irritating. Suitable solutions prepared from the liquefied gas, a process which at present is very much simplified, possess necessarily all the drawbacks of an aqueous solution.

The usual solutions which have been most widely employed are Labarraque's

solution, *i.e.* a solution of chlorinated soda, and Javelle water. These two solutions, however, possess also serious drawbacks as far as their clinical application is concerned. They readily deteriorate, and, incidentally, they macerate the epidermis when kept in contact therewith even for a short time only, so as to render them practically not only useless but directly dangerous for the purpose for which they are intended.

Dakin in his studies of the antiseptic properties of the hypochlorite of soda solution finally succeeded in preparing a compound which is practically neutral and which incidentally contains only about $\frac{1}{2}$ per cent. of the hypochlorite salt. This solution produces virtually no irritating action on the skin and wound surfaces, and it is the compound which at present, according to the Carrel-Dehelly-Depage technique, is employed in the treatment of war wounds. Without entering into a discussion of the complicated and time-consuming technique of the above method as utilized in general surgery, it suffices to say that the method as well as the solution employed is practically useless for the treatment of infected root-canals.

Dakin soon realized the clinical drawbacks possessed by the various solutions of chlorinated soda, and his further studies led him to utilize certain synthetic chlorin compounds discovered by Chattaway, among which chloramin-T and dichloramin-T are the two most important representatives. Chloramin-T, being water-soluble, possesses more or less the same disadvantages as any other aqueous solution of chlorin. The permanence of such solutions is very limited, and, further, they are very quickly exhausted by wound secretions. On the other hand, dichloramin-T, a substance soluble in an oily medium, furnishes a veritable reservoir for the slow elimination of chlorin which preserves its activity for many hours in the presence of wound exudates. It is this latter substance which, upon the recommendation of Captain Sweet, we selected from the various chlorin compounds for our experimental work, and the results ob-

tained therewith merely verified the praiseworthy reports published by Dr. W. E. Lee and his numerous co-workers.

Dichloramin-T is the abbreviated name of para-toluene-sulfone-dichloramid, $\text{CH}_3\text{C}_6\text{H}_4\text{SO}_2\text{NCl}_2$. (The letter T, indicating toluene, distinguishes it from similar compounds which have been or may be made from benzene, xylene, etc.)

Graphic formula.

It is a yellowish-white crystalline powder, having a sweetish, rather pungent chlorous odor and containing a little over 29 per cent. of available chlorin. It melts at about 80° C. (176° F.). In the solid state, when kept in the dark it is stable. It is practically insoluble in water, but is readily soluble in most organic solvents, *i.e.* chloroform, benzene, eucalyptol, etc. It quickly reacts, undergoing decomposition with evolution of nascent chlorin when brought into contact with most organic substances, such as acids, alcohol, and the amines, with hydrogen dioxid, water, etc., and certain metals. It should be stored in small amber-colored glass-stoppered bottles and protected from heat.

The strength of dichloramin-T or its solutions may be readily estimated by taking an aliquot quantity, *i.e.* 0.1 gram of dry dichloramin-T or 0.5 gram of its solution and adding 5 cc. of carbon tetrachlorid and an excess of a 10 per cent. potassium iodid solution and glacial

acetic acid. The liberated iodine is titrated with N/10 sodium thiosulfate solution. Each cc. of the thiosulfate solution is equal to 6 milligrams of dichloramin-T. A strong odor of chlorin and incomplete solubility in chloroform are reliable signs of decomposition of the salt, while extreme turbidity and the formation of crystals in the bottom of the bottle are an indication of the decomposition of its solution in chlorococane.

The bactericidal action of dichloramin-T is discussed under the heading of "General action of antiseptics."

SOLVENTS FOR DICHLORAMIN-T.

At the early stages of our experimental work we prepared the dichloramin-T solution in accordance with the original suggestion of Dakin, by using such solvents as chlorinated eucalyptol and chlorinated paraffin oil, or a mixture of both. However, it was observed that these solutions produced varying degrees of pain, which we attributed to the irritating effects of the solvents. Chlorinated eucalyptol is an unstable body which readily decomposes in the presence of dichloramin-T by absorbing moisture, resulting in the production of volatile acid substances. Hence, when Dakin announced that he had prepared a new solvent for his antiseptic which eliminated the above disadvantages of the original solvents, we at once tried out the preparation and found it to be fully in accordance with the claims made for it.

This new compound is known as "chlorococane." It is a bland, heavy, viscid oil, having a slight yellowish color, and is prepared from hard paraffin melting at about 50° C. (122° F.) by replacing a part of its hydrogen by chlorin. Chlorococane does not contain any "free" chlorin, although it absorbs from 45 to 55 per cent. of its own weight. The chlorin combines with the carbon of the paraffin somewhat in the same manner as chlorin and sodium combine to form the ordinary inert sodium chlorid. Chlorococane, by the application of moderate

heat, will readily dissolve from 8 to 10 per cent. of dichloramin-T, which is more than amply sufficient for dental purposes. As the preparation is too cumbersome to be attempted by the dentist, chlorcosane, as well as dichloramin-T, is best procured through the ordinary trade channels.

PREPARATION OF DICHLORAMIN-T SOLUTION.

Regarding the concentration of the solution of dichloramin-T for the purpose of treating infected root-canals, we have found that a 5 per cent. solution of the salt in chlorinated paraffin, *i.e.* chlorcosane, answers our purpose quite satisfactorily. We have heard an opinion expressed to the effect that a 5 per cent. solution is too irritating when used in root-canal work. We cannot subscribe to such assertions; we rather believe that the pain resulting from its application was due to two causes—a spoiled solution and a faulty technique. Dr. Lee and his co-workers have employed a 5 per cent. solution in many thousands of cases by pouring quantities of a dram or more directly into an open wound without producing the slightest painful sensation. We can fully confirm these facts.

Solutions of dichloramin-T preserve their activity for a limited time only; they usually deteriorate within two or three months, and therefore it is best to prepare a convenient quantity which may be readily used up within a month or so. To prepare an ounce of the solution, 25 grains of dichloramin-T are placed in a dark amber-colored glass-stoppered bottle, which must be absolutely clean and free from moisture. One ounce of chlorcosane is added, the whole is thoroughly shaken, and the bottle is placed in a pan containing very hot water or upon a radiator or other source of indirect heat. Within a quarter of an hour complete solution usually results. Direct heat in making the solution is to be avoided, as it is liable to injure the compound. The solution is immediately ready for use; filter-

ing is not necessary. As stated above, only dark amber-colored or black bottles should be employed as storage vessels; blue glass does not protect the solution against the actinic effects of strong light.

Solutions of dichloramin-T must be carefully protected against heat, light, water, alcohol, and most metals; in fact, most common substances have a strong affinity for chlorin, hence the ready decomposition of this solution when brought in contact therewith. Whenever the solution becomes turbid and forms a deposit of crystals in the bottom of the bottle, or develops a pronounced odor of hypochlorous acid, it should be

FIG. 1.

Office-preparation bottle.

discarded. Fresh solutions, if chilled, may temporarily become cloudy, or even precipitate, owing to the separation of either dichloramin-T or of solid paraffin. Slightly warming the solution quickly restores its usefulness.

For office purposes, it is best to keep the dichloramin-T solution in an amber-colored office-preparation bottle with a ground cap. (Fig. 1.) A small glass rod or tube kept in the bottle readily assists in obtaining the few drops necessary for each treatment, to be placed upon an aseptic glass tray. Under no condition should pliers charged with cotton, etc., be introduced into the preparation in the bottle, and no unused portions of the solution must be returned to the stock-bottle.

GENERAL ACTION OF ANTISEPTICS WITH
SPECIAL REFERENCE TO DICHLORAMIN-T.

The terminology of the substances which are used for the purpose of combating infection is frequently employed in a very loose manner, and without regard to its precise meaning. Hence, therefore, it may not be amiss to give as a preamble the definite significance of the more important terms as they are used to designate the specific nature of their action.

It is generally recognized at present that the breaking down of highly organized bodies is brought about by the activity of minute vegetable organisms—the bacteria. This process is known as putrefaction, or, under certain conditions, as fermentation. The presence of certain bacteria and their products is instrumental in the production of severe physiologic changes resulting in the various vital phenomena known as infectious diseases. The existence of a condition in which bacterial infection and its sequelæ are brought about by the presence of germs or their products is referred to as sepsis, while asepsis implies the entire freedom from such infection. If a primarily septic condition is changed by some method or means which inhibits the growth of the putrefactive organism, antiseptics is induced. Antiseptics, therefore, are chemical agents which merely inhibit the action and growth of bacteria, while germicides destroy the vitality of the infective organisms. Disinfectants also kill the bacteria, and incidentally chemically change their poisonous products to some inert compound. A disinfectant must, therefore, be a germicide, while an antiseptic is not necessarily a germicide nor a disinfectant.

According to Dakin and Dunham, the action of chlorin upon bacteria and their products seems to depend upon a process of chlorination, *i.e.* the amino acid groups of the proteins readily attack all substances containing "active" chlorin in such a way that the hydrogen attached to the nitrogen atom is replaced by chlorin. The newly formed compounds

contain the NCl group, and therefore belong to the class of chloramins.

The chlorin of these newly linked compounds is still available, and these substances themselves are active germicides. A part of the liberated chlorin is used up by forming inert compounds, that is, chlorin unites with carbon to form inert chlorids. Incidentally, the liberated chlorin is a strong oxidizing (bleaching) agent which is a most beneficial factor in the treatment of pulpless teeth. Chlorin further acts as a prompt deodorizing agent, and possesses the additional remarkable property of digesting and removing sloughing necrotic tissue and of decomposing toxins.

Dichloramin-T shares with other chlorin compounds the property of being a very active lymphagogue, *i.e.* the amount of wound secretion, especially in the beginning of the treatment, may be considerably increased. The writer's attention has been frequently drawn to this fact by fellow practitioners who have tried the compound in treating root-canals, and who complained of the increased secretion from the canals—which, incidentally, influences the granulation of the wound most beneficially.

The application of the antiseptic principle as utilized in wound sterilization depends primarily upon three definite conditions:

- (1) Absolute contact of the antiseptic with the infecting organism.
- (2) Time during which this contact is maintained.
- (3) Sufficient concentration of the antiseptic at the points of contact.

Absolute contact between the antiseptic agent and the substances to be acted upon must be rigidly observed, as no antiseptic is known to act at a distance. Consequently all dead tissue (in our particular instance, the débris of the

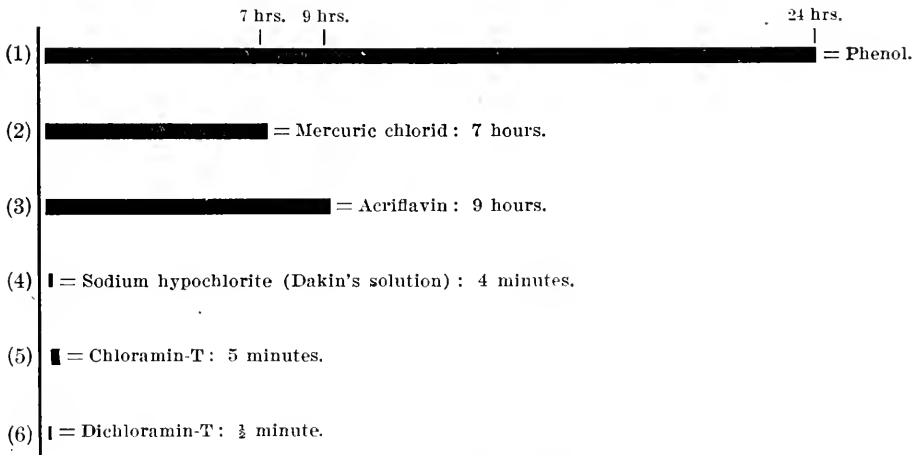

gangrenous pulp) must be mechanically removed. Regarding the factor of time, it must be understood that the action of the antiseptic is enormously influenced by the medium in which it is dispersed, *i.e.* a specific solution of one antiseptic may kill a given number of bacteria suspended in water very rapidly, while this same solution upon bacteria suspended in blood serum may be practically insignificant. The stability of an antiseptic as an inherent property is also of vital importance, since the innumerable changes which it undergoes during its action, such as decomposition, precipitation, absorption, etc., are of extremely wide variation. Dr. Dunham has very ingeniously depicted the speed of disinfection of a few widely used antiseptics in the following chart:

tained from clinical observation. The concentration of the antiseptic solution determines its mass action which can be safely employed for tissue sterilization.

Concerning the relative bactericidal properties of the dichloramin-T solution, Drs. Lee and Furness make the following comment:

Theoretically, then, this new chlorin compound eliminated at the start the chief indication or necessity for the Carrel technique, skin irritation. With such a solution it should be possible to present to an infection an overwhelming mass of germicide, a 20 per cent. solution of dichloramin-T being approximately 80 times the germicidal mass of a 0.48 per cent. hypochlorite solution. There is a vital necessity, when using germicides in the treatment of infections, for the earliest possible application of an overwhelming mass

FIG. 2.

SPEED OF DISINFECTION.

A 2 per cent. solution of (1) Phenol failed to sterilize the mixture in 24 hours, although the surviving organisms were only two per thousand of those originally present. (2) Mercuric chlorid, 1:1000, accomplished the same degree of disinfection in three hours, and completely sterilized in seven hours. (3) Acriflavin, a dye recently introduced as an antiseptic, 3:1000, killed all the bacteria in about nine hours. (4) Sodium hypochlorite (Dakin's solution), 0.5 per cent., completely sterilized in four minutes. (5) Chloramin-T in five minutes. (6) Dichloramin-T, 2 per cent. in oil solution, in less than half a minute when well mixed with the septic material. (Dunham.)

Finally, the permissible concentration of an antiseptic depends largely upon the tolerance of the tissues with which it is brought in contact, and is usually ob-

of a rapidly acting agent, because infection develops in the tissues at the rate of a geometric progression, and not by the slow process of addition, and therefore every min-

ute counts in the end result. Dichloramin-T, with a phenol-oil coefficient of about 50, can be presented in a larger mass without injury to the tissue cells than any other germicide we have used. Instead of having this chlorin given up with explosive rapidity and the consequent necessity of frequent renewals of the solution, it would be slowly diffused into the surrounding media, making it unnecessary to renew the solution or to dress the wounds more frequently than once in every twenty-four hours.

TECHNIQUE OF TREATMENT OF INFECTED ROOT-CANALS.

The treatment of an infected root-canal when viewed in the light of modern

in the removal of the debris of a dead pulp are so well known that we are able to dispose of this phase of the treatment with a very few words. After the root-canal is thoroughly opened under aseptic precautions, a droplet of dichloramin-T is placed in the pulp chamber, and with sterile broaches and most careful manipulation its contents are removed. The sterile broaches are alternately dipped into dichloramin-T, slowly worked into the canal, and wiped on a piece of cheesecloth or bibulous paper. Extreme care should be exercised to avoid forcing any of the gangrenous material beyond the foramen, otherwise a violent infection,

FIG. 3.

Aseptic medicament tray.

conservative dentistry resolves itself into three definite phases—the mechanical, the chemical, and the therapeutic procedure. If these various steps are carried out in regular sequence, definite results should be obtained within a very limited period of time, manifested as a cure, or, if negative, in subjecting the tooth to the last resort of treatment, a surgical operation. This latter procedure may consist in the removal of the diseased root-end by excision (root amputation) as described by the writer in a recent article,* or if the diagnosis does not favor such conservative procedures, in its radical cure—extraction of the tooth.

The mechanical procedures involved

which usually manifests itself within twenty-four hours in the form of an acute abscess, is sure to follow. If the operator is fortunate enough at the first sitting to reach the apical end of the canal, the subsequent treatment will be very much simplified, while if the reverse is true, the patient should be dismissed with a dressing of dichloramin-T sealed in the canal. If at the first sitting no attempt is made to remove the contents of the canal the latter should not be sealed, as there is always a possibility of renewed activity of the aerobic bacteria as a sequence of oxygen having entered into the canal, which results in the production of gas and subsequent pressure along the line of least resistance, namely, the apical foramen.

As a convenient means of holding the necessary drugs, sterilizing broaches, etc.,

* See DENTAL COSMOS for May 1918, page 381.

the writer has suggested an aseptic medicament tray, as shown in Fig. 3. The elongated depressions in the tray are filled with a mixture of four parts of alcohol and one part of glycerin, in which broaches, root-canal cleansers, etc., may be kept immersed while working on the tooth.

It must be borne in mind, however, that the mechanical removal of the debris of a decomposed pulp from a root-canal forms the most important procedure in its routine treatment. It is a gross fallacy to assume that neglect in this respect can be counterbalanced by the future use of antiseptics. To depend upon a chemical agent to perform that portion of the work which should be done by mechanical means, is a misinterpretation of the bactericidal action of antiseptics. At best, antiseptics are only accessories to, and not substitutes for, efficient mechanical procedures. In conformity with the laws governing the action of antiseptics it must be repeated that the antiseptic power of germicidal solutions is practically restricted to that portion of the root-canal with which they actually are brought in contact—at best a very superficial process—and no antiseptic seems to possess any considerable power of penetration without simultaneously losing its activity.

It should be an invariable rule with the operator to enter a root-canal only with absolutely sterile broaches, absorbent-paper or cotton points, etc. A convenient and simple sterilizer for absorbent points and gutta-percha points has been recently devised by the writer: A screw-cap bottle of about one ounce capacity is provided with a piece of thick cotton roll of about one inch in length (Fig. 4), which is fastened to the interior of the cap with sealing-wax. About five drops of dichloramin-T solution are placed upon the lower end of the roll, where they are quickly absorbed. The chlorin compound is renewed about once a month. The paper, cotton, or gutta-percha points are placed in the bottom of the dry bottle, the screw cap is put into position and the permanent sterilizer is completed. The efficiency

of this simple device has been repeatedly tested by plating out the points; they have always been found to be absolutely sterile.

The chemical treatment of the infected root-canal, and incidentally its enlargement when obstructed, should invariably immediately follow as the second stage in the routine sequence. Schreier, in 1893, advocated an alloy of potassium and sodium (kalium-natrium) for such purposes, and the late Dr. John R. Callahan, in the same year, introduced the use of 50 per cent. sulfuric acid. The sulfuric acid method enjoys

FIG. 4.

a, Paper-cone sterilizer. *b*, Gutta-percha point sterilizer.

at present a wide popularity, although other acids, *i.e.* 10 per cent. hydrochloric acid, pure nitro-hydrochloric acid (aqua regia), and phenol-sulfonic acid have been recommended. The therapeutic absurdity of the latter compound has been dealt with by the writer on a former occasion.*

Pure nitro-hydrochloric acid, as introduced by G. W. Weld in 1897, is the most efficient agent for the above purposes. On account of its strong caustic properties, extreme care is required in handling it. This acid should be preserved in glass-stoppered bottles and preferably kept outside of the operating

* See DENTAL COSMOS for April 1912, page 397.

room, as its fumes are most destructive to metallic instruments. It may be applied by means of a steel broach. Concentrated aqua regia has practically very little effect on steel, as the broach is at once covered by a protective coat by the action of the evolved nitrosyl chlorid, which checks the further action of the acid upon the metal.

Whatever acid is employed should be neutralized by sodium dioxid, as recommended by Kirk in 1894, and not by sodium bicarbonate, which is practically useless for the above purposes. This agent is carried into the root-canal by means of a broach previously dipped into chloroform: the latter substance merely acts as an indifferent conveyer of the sodium dioxid to the root-canal, which, if water or ordinary alcohol is used, readily decomposes. The chemical interchange between the various acids may be portrayed by their respective reactions as follows:

The evolution of nascent oxygen which follows as a sequence of the reaction between the sodium dioxid and any of the acids employed is an important factor in the chemical treatment of the root-canal, as it will materially assist in the preservation of the natural color of the tooth. Copious washing of the canal with water should be followed by the removal of moisture. Sterile paper points assisted by a few drops of acetone, hot air, or a heated silver wire are serviceable for this purpose. Overheating of the tooth must be carefully avoided: however, a fair dryness of the root-canal must be insisted upon, as otherwise the future treatment with dichloramin-T is materially impaired. A suitable paper point is now saturated with dichloramin-T, carried to the root-canal, and with a pumping motion an attempt is made to coat the walls of the latter, and if possible a droplet is forced into the peri-

apical space. The use of the warm air blast is of material assistance in getting the oily solution into the finer ramifications of the canal. The warm air blast is recommended in this connection solely for its mechanical effect in aiding the diffusion of the dichloramin-T throughout the dentin, but its use as a means for previous desiccation of the canal walls is not admissible, for the reason that the natural moisture of the tooth structure is necessary to the production of nascent chlorin resulting from the reaction of the dichloramin-T with the water of the organic structure of the tooth.

A fresh point carrying a drop of the chlorin solution is now slowly forced into the canal to its very end and immediately sealed with a suitable retainer.

As we have stated above, close contact of the antiseptic solution with the walls of the root-canal, and if possible, with the surface of the involved infected area within the periapical tissues, is essential to obtain therapeutic results.

The first application remains undisturbed for twenty-four hours. At the return of the patient the point is removed aseptically and carefully examined, and if found discolored a second acid treatment is necessary.

The second dichloramin-T treatment placed in the dry canal, again remains twenty-four hours, while a third application is usually left in position for forty-eight hours. The paper cone removed at the last sitting must show no discoloration, it must have a distinct odor of chlorin, and it must be fairly free from absorbed exudates. Under no consideration should a first or second treatment be left in the canal over twenty-four hours; at the end of this time the chlorin compound is completely exhausted, and usually a pronounced flow of lymph, as referred to above, is the sequence. If at the last treatment the canal is found satisfactorily clean, no time should be lost in filling it at once.

In all cases in which the infection from the root-canal has passed into the periapical space, localized pathological disturbances arise which may lead to the formation of an alveolar abscess. The

content of the abscess cavity is usually forced to the surface along the lines of least resistance, *i.e.* either through the root-canal or through the bony wall of the alveolus and thereby establishing a fistula. In either case the treatment does not differ from the above-discussed principles.

In cases in which a fistula exists, an effort is made to establish a communication between the root-canal and the fistula proper by forcing normal saline solution through the fistula via the root-canal. Dichloramin-T solution is now pumped through the root-canal into the fistula until it appears at its orifice. In from twenty-four to forty-eight hours after the first treatment the external opening will usually be found closed. The treatment of a granuloma, *i.e.* the product of a chronic proliferating pericementitis, does not differ from the routine procedure. It should be understood, however, that the dichloramin-T solution must actually pass through the foramen into the periapical space so as to be brought into close contact with the walls of the granuloma.

THERAPEUTIC EVIDENCE.

Regarding the existing sterility of a primarily infected root-canal as treated by the above-outlined dichloramin-T method, it should be emphasized that rigorous bacteriological tests were made in numerous instances by plating out scrapings from the walls of the canals before and after they had been pronounced clinically ready to fill. These tests consisted in subjecting the scrapings to incubation upon agar plates, bouillon, etc. After exposure in an incubator for various lengths of time, usually from forty-eight to seventy-two hours, it was observed in all instances that the growths from these scrapings of the treated canals were negative, *i.e.* no cultures were obtained.

"The day of authority in any branch of science has gone by;—statistics on the table, please." This eminently logical dictum of Prof. Karl Pearson portrays a sound scientific doctrine, and it should

be insisted upon as the crucial test of therapeutic evidence of any new remedy. In the discussion of the clinical efficiency of a drug, the *post hoc ergo propter hoc* type of logic is only too apt to creep in, which naturally leads to a biased reasoning. The raw material of science consists of unconformable facts, hence the logic of Aristotle, which ignores this evidence, must be forsaken in an inquiry into the efficiency of a therapeutic agent. On a former occasion, regarding the methods of research, we have stated that—

In investigation into a remedy, or, for that matter, any biologic problem, the following four rules of research must be observed:

(1) Generally known observations or facts are collected.

(2) Hypotheses are drawn from these observations, and are explained.

(3) Other crucial facts (experiments) are collected to test these hypotheses, and

(4) A second set of facts is collected, and from it are drawn the final conclusions or verifications.

Omitting one of these rules or applying illogical reasoning based on analogy, or inductive instead of deductive methods, leads to a false analysis of the problem under consideration.

The final proof of therapeutic efficiency rests upon the application of the remedy to the patient in conformity with the good old truism, "The proof of the pudding is in the eating." However, the real problem is by no means fully substantiated by clinical evidence only; a causative connection between the remedy and the event has to be established.

The question now arises, What proofs have we in regard to the therapeutic efficiency of dichloramin-T in the treatment of infected root-canals?

(1) *General known observations.* Up to the present (October 1918) Dr. Lee and his co-workers announce that "Records have been obtained from 19,040 completed cases in civil surgical practice which have been treated with this agent, and Captain Sweet, U.S.A., base hospital No. 10, France, in July 1917 obtained the records of a total of 4903 cases treated with the preparation."

(2) *Hypotheses drawn from these observations.* Since the infection of a root-canal and the subsequent suppuration of the periapical tissues does not differ from any other wound infection, it is *a priori* logical to assume that the remedy is also suitable for the treatment of such cases.

(3) *Crucial experiments to test these hypotheses.* Bacteriologic tests of the infected root-canals before and after treatment verify the general claims made for the therapeutic efficiency of dichloramin-T.

(4) *Final verifications drawn from a second set of collected facts.* After one year of observation, clinical inspection of a set of experimental cases, verified by roentgen pictures taken at suitable intervals before and after treatment, pronounces the complete eradication of the initial disease focus, hence a cure.

CASE HISTORIES.

Aside from the momentous question of sterilizing an infected root-canal, the eradication of the sequences of pulp gangrene, *i.e.* apical infection, is equally as important. Here the innoxiousness of the employed drug is especially of vital significance, hence all such compounds as exercise a deleterious influence upon the soft periapical structures must be rigidly avoided. Compounds which are generically classified as caustics, such as concentrated solutions of formaldehyd, phenol, the mineral and certain organic acids, and most metallic salts, should not be employed for the treatment of infected periapical tissues; they produce necrotic areas which furnish a suitable pabulum for those organisms contained in the deeper structures which have not been destroyed by these superficial coagulants, and, incidentally, most metallic salts produce marked discoloration of the tooth structure.

The eradication of infected foci about the apices of teeth by the application of drugs is an extremely mooted question. Aside from the results obtained with electro-sterilization, *i.e.* the utilization of available chlorin, the writer is not aware of any other drug or drug compound,

except dichloramin-T, which accomplishes this purpose. Experimentally, proof can now be furnished that infected apical areas, and even granulomas, may be completely eradicated by the application of dichloramin-T solution, provided that the solution is brought into intimate contact with the infected zone. A few cases selected from several hundred clinical records will amply justify this statement.

Case I. Miss S. F., twenty years, presented herself on November 6, 1917. The lower left first molar, having a gold shell crown, was tender on pressure; occasionally swelling near the apical region with paroxysmal pain at

FIG. 5.

FIG. 6.

FIG. 7.

various times. A roentgenogram of the tooth showed a large rarefied area near the apices of the two roots, incomplete root-fillings, and an ill-fitting crown. (See Fig. 5.)

Treatment: Removal of crown and root-fillings, sulfuric acid and Na_2O_2 treatment and

FIG. 8.

dichloramin-T application. The latter was renewed four times at intervals of about forty-eight hours. As this was an experimental case we did not fill the root-canals at once after the last treatment. A second radiograph was taken on January 9, 1918, with the following results: Rarefied area had become lighter and smaller in second picture. (Fig. 6.) Pain had subsided. Bacteriologic examination of root-canals negative. The root-canals were filled. Radiogram taken on April 30, 1918, with the following results: Rarefied area very much reduced. (Fig. 7.) A new shell crown was now put over the tooth, and the last picture taken, on June 17, 1918, with the following results: Rarefied area reduced to a light shadow. (Fig. 8.) Tooth has given perfect satisfaction. On inspection, October 2, 1918, no visible disturbance noticed. Patient refuses to have another X-ray taken.

Case II. Mrs. M. H., forty-five years. Lower second premolar has a metal filling.

FIG. 9.

The tooth reacts painfully at intervals; sore on tapping. Roentgenogram shows a marked rarefied area about the apex. (Fig. 9.)

Granuloma? On opening the tooth, the canal was found to contain a small quantity of pulp debris. Routine treatment as above; three applications of dichloramin-T. Bacteriologic examination negative. Root-canal filled June 6th.

FIG. 10.

About one year later, May 22, 1918, patient returned for a second roentgen picture. Tooth perfectly sound. X-ray picture shows a complete clearing up of original rarefied area. (Fig. 10.)

Case III. Mrs. E. W. Sch., age forty years. First and second left premolars sore on pressure: occasional swelling. X-ray, August 1, 1917. (Fig. 11.) Roots opened and left

FIG. 11.

FIG. 12.

open for twenty-four hours. August 3d. routine treatment with sulfuric acid and sodium dioxid. Three treatments with dichloramin-T. Roots filled August 8, 1917. (Fig. 12.) A

roentgenogram taken June 12, 1918, shows eradication of infected apical foci. (Fig. 13.)

FIG. 13.

SUMMARY.

Upon the solicitation of the writer, dichloramin-T has been tried by numer-

ous practitioners, and it has been extensively employed during the session of 1917-18 by the students in our infirmary. The results obtained therewith have been most satisfactory. Basing his assumptions upon the logical sequence of the above-discussed method of investigation and the clinical results obtained with this compound by him and by fellow practitioners, the writer feels justified in recommending to the profession the use of this agent for the treatment of infected root-canals and their sequelæ. On account of its effectiveness, its extreme simplicity of application, and its innocuousness, dichloramin-T is superior for the above purposes to any other drug so far known.

40TH AND SPRUCE STS.

Primary Factors in the Etiology of Periodontoclasia.

By JOHN OPPIE McCALL, D.D.S., Buffalo, N. Y.

(Read before the Maryland State Dental Association, Baltimore, June 5-7, 1918.)

THE attorney who presents his case in a court of law usually prefaces his argument with a statement of the points which he proposes to make, thus focusing the attention of his hearers on the principal features of his discourse, and showing the relationship between matters which might otherwise seem disconnected. So I, though not an attorney, but as your essayist for this session, shall first present to you briefly the main features of my paper, in the hope that in this manner I may best serve the coherence and force of my argument.

The most important point which I wish to make is that the etiology of periodontoclasia is a mixed etiology—that is, at least two causative factors must combine to bring about the destruction of the supporting tissues of the teeth; and moreover, that factors both for and

against the health of these tissues must be considered. Next comes the distinction suggested by my title, the division of etiological factors into primary and secondary, with the natural focusing of attention on the group of primary factors.

I wish also to call to your attention the accomplishments of present-day periodontia—the elimination of inflammation and infection around the teeth; the elimination of so-called pockets by the vital attachment of gingival tissue to the root surface; the growth of new bone to at least partially replace bone destroyed through periodontal disease. As a corollary to this I request your very serious consideration of the practicability of the prevention of periodontal disease, not by the specialist alone, but by the general practitioner, with particular refer-

ence to the responsibility we must all assume for the loss of teeth not attacked by periapical infection.

While this paper is not to deal primarily with the pathology of the periodontal tissues, it is impossible to consider the etiology of periodontoclasia without suggesting a revision of the somewhat vague pathology and classification of periodontal diseases exhibited in most of our current dental writings, for the purpose of bringing the entire group of ailments commonly known as "pyorrhea alveolaris" into an orderly concourse well within the comprehension of the average dental practitioner.

Before embarking on the elaboration of these points I should like to call to your attention the distinction commonly made between a fact and an hypothesis, and the place that each occupies in science. A fact is something which has been proved and can at any time be proved to be true. Naturally in dealing with any of the branches of physical science it is highly desirable that our concepts should be based on facts, or at least be susceptible of proof. An hypothesis is an assumption, which may not have been proved and may not even be susceptible of proof, but which accords with some of the known facts on which it bears. A concept which accords with *all* known facts may properly be accepted as being true, and may also be taken as a foundation for the formulation of theories regarding various groups of related phenomena. One of the fundamental hypotheses of natural science is that proposed by Avogadro regarding the number of molecules in equal volumes of gases. Avogadro's hypothesis will probably never be proved, yet upon this assumption is erected the towering structure of modern chemistry, because it accords with all known facts of chemical science.

In the course of the development of medical and dental science many hypotheses have been proposed. If they have always tallied with fact, then they were correct. And many hypotheses have been accepted and later proved—as, for instance, the assumption regarding the or-

ganism responsible for malaria. On the other hand, many hypotheses have been found to be accordant with only part of the facts, and have had to be rejected, as the assumption that the *endamoeba buccalis* is the specific cause of dental periclasia. We must always bear in mind, too, that theory must adjust itself to fact, not fact to theory. In other words, if a phenomenon always occurs in the same way and under the influence of the same causative factors, any theory which does not agree with that sequence of events, no matter how plausible it may seem, must be rejected or remodeled to fit the facts.

No one could wish more ardently than you essayist that out of the maze of speculations of the past an orderly proven set of facts might be presented to you regarding the causation of periodontoclasia. Study of the etiology of this group of dental disorders has revealed the interaction of many factors of widely divergent types, making this etiology nearly as complex as, for instance, the parasitology of the mouth—so complex, in fact, as to make its reproduction in the field of animal experimentation very nearly an impossibility, thus making the proving of our hypotheses enormously difficult. It is, however, a well-known axiom that the successful treatment of disease lies in the removal of the cause; thus an assumption regarding etiology may be considered to be correct if uniformly successful results follow its application. And it is upon this uniform sequence of diagnosis, treatment, and result, not only in my own hands but in the hands of many others, that the hypotheses I present to you have been built up. The acid test for the correctness of these assumptions lies in the success with which others may apply them in their own practices. This calls for a word of caution. Remember that it is easy even for the specialist to overlook one out of several contributing etiological factors present, hence the great possibility of an incomplete diagnosis by the untrained observer, with the consequent failure to obtain results. Remember also that root surgery, which is involved in practically

all treatment, must be perfect in its execution; this requires temperament as well as an exacting technique on the part of the operator.

The attempt to apply the principles laid down in this paper by the general practitioner will thus be apt to meet with only partial success, especially if he applies them first, as he is very likely to do, in the treatment of his advanced cases. Failures thus encountered do not of course invalidate the hypotheses I propose; on the contrary, these failures may be turned into stepping-stones which, with persistent study and improvement in technique, will lead to the uniformly successful results obtained by others.

ETIOLOGY OF PERIODONTOCLASIA.

The etiological factors responsible for the various disorders to which we give the generic name "periodontoclasia" may best be considered in groups, thus avoiding the confusion which would otherwise be inevitable. These groups are as follows:

- (1) Malocclusion.
- (2) Defective operative and prosthetic procedures.
- (3) Trauma.
- (4) Abnormality of tooth surface.
- (5) Parasitic invasion.
- (6) Abnormal systemic conditions.

The first four are the groups which I call primary, the fifth and sixth being secondary. I have felt it necessary to call these primary and secondary factors, rather than predisposing and exciting, as is the common practice in pathology, and for this reason: There are several factors which are incapable of inaugurating a disease process in the periodontal tissue, yet which are directly concerned with the production of some of the typical phenomena of the disease, and which thus may properly be called exciting causes. For instance, bacteria are incapable of proliferating in a healthy or hypertonic tissue: they accordingly cannot be a primary cause of periodontoclasia. Yet the severing of the pericemental fibers with resulting pocket for-

mation does not take place unless bacteria invade this tissue and proliferate within it. Bacteria are thus seen to be a true exciting cause of this type of dental periclasia, the primary factor on the other hand being something which lowers the tone and hence the resisting power of the tissue.

It may be argued that the term predisposing is virtually synonymous with primary. This might be true if a predisposing cause was always a predisposing cause. But we find that the same factor may be a predisposing cause in one case and an exciting cause in another. But a primary cause is always a primary cause. Then again, to use the terms predisposing and exciting usually means that we give our attention principally to the exciting cause, often forgetting that the exciting cause is inoperative except as it is preceded by the predisposing cause. And I think our medical brethren are occasionally guilty of the same error. To use the term primary on the other hand focuses our attention on the important and determining factor.

Our primary factors in about the order of their importance, are malocclusion, defective operative and prosthetic procedures, trauma and abnormality of tooth surface. We will now consider these groups in detail with their subdivisions.

MALOCCLUSION.

Malocclusion as a factor in dental periclasia has three subdivisions, *i.e.* traumatic occlusion, defective approximal contacts, and labio-lingual malposition. Traumatic occlusion is a term suggested by Dr. Paul R. Stillman to apply to any form of malocclusion whereby the tooth or teeth are driven beyond the normal limits of movement within their sockets during contact with their antagonists in closing or in movements of mastication. It is at once the most destructive factor in dental periclasia, and usually the easiest of prevention in any practice in which the teeth are under observation and control from infancy on through adult life. A whole essay could well be

written on traumatic occlusion, but I shall here try to bring out simply the main points regarding this destructive agency. There are three ways in which the periodontal tissues may receive an occlusal trauma, viz, excessive impact on one or more cusps through elongation or rotation; impact at an angle to the long axis of the root through tipping, as after extraction; and a thrust to one side of the socket due to an elongation or closing up of the bite in the incisal region, or inharmony of the inclined planes in the bicuspid and molar region. The commonest causes of traumatic occlusion are malocclusions of the Angle classification, extractions without retention of space, lack of normal wear of cusps with advancing years, and faulty operative and prosthetic restorations. Extraction, unless the space is retained by an orthodontic retainer, denture, or bridge, will result in drifting and tipping of the remaining teeth, and a closing up of the bite, bringing an impact at an angle to the long axis of the tipped teeth and excessive stress on the anterior teeth, to say nothing of the opening up of contacts. A greater variety of traumatic occlusions may be brought about by extractions than through any other one operation.

Faulty dental operations bring about traumatic occlusion in a surprising number of cases. Fillings are built just a little too high; occlusal surfaces are not carved to retain normal occlusion, thus permitting the teeth to drift; the lingual surfaces of upper anterior crowns are made a little too full. But more particularly is damage done in the much-berated field of crown and bridge work through making occlusal surfaces too high or through failure to plan for the various movements of the mandible. Occlusal trauma thus instituted is 100 per cent. more destructive than ill-fitting bands, the lack of individual movement of abutments, and uncleanness, to which so much has been charged in the past. Failure to recognize the part played by traumatic occlusion in virtually pounding crowns and bridges out of patients' mouths, is largely responsible for the

muddle in which the crown and bridge branch at present finds itself.

Clasps and Gilmore attachments, used for partial dentures, often produce a tipping effect or side-thrust during mastication which constitutes a very serious trauma. Wing bridges and excessive contacts without an occlusal rest on the adjacent tooth do much damage also. Failure to wear down high cusps of the natural teeth with advancing years often means the continuance of a heavy side strain in the movements of mastication to the point where it becomes an actual trauma. Malocclusion according to the Angle classification does not necessarily mean traumatic occlusion, but mouths in which any abnormality of occlusion exists should be carefully scrutinized for the presence of teeth so placed as to meet their antagonists a little to the buccal or lingual of their proper position; teeth tipped labio-lingually or bucco-lingually; rotated teeth; and excessive overlap in the incisal region.

In the case of most causative factors the method of correction will be suggested simply by calling attention to the cause itself. In the case of traumatic occlusion this may not be so obvious. The carborundum stone guided by articulating paper is the agent most often used, elongated teeth and high cusps being shortened, and occluding surfaces being reshaped to give harmony between the inclined planes of the opposing teeth, as for instance the dressing down of the labial surfaces of the lower incisors. In cases where a number of teeth have been lost or there has been excessive abrasion, it may be necessary to open the bite if the above method would entail an excessive cutting of tooth structure. In regard to crown and bridge work let me suggest that the beginning of the traumatic occlusion comes in taking the bite. Inspection of the occlusion of teeth not covered by the wax both before and during the taking of the bite will enable the operator to detect errors in this step. When the bridge is inserted, be sure that the teeth in the mouth occlude the same as before insertion, and be sure that the bite on all the teeth feels natural to the

patient. The final decision on this can only come after the eating of several meals. The bridge that feels like a stone wall in the mouth is one which does not occlude properly.

Damage done by open or improper contacts has been very fully considered in the past, and need not be enlarged upon in this paper. It is well to point out one fact with regard to open contacts not previously emphasized, namely, that damage is done not only by impaction of food, but by the loss of necessary mesio-distal support, thus permitting a movement of the teeth which leads to a real traumatic occlusion.

Labio-lingual malposition when not a cause of traumatic occlusion or of defective contacts between adjoining teeth is a factor in periodontoclasia, because it increases the difficulty of keeping the tooth surface clean. This condition is often found in the lower incisal region due to narrow arches with consequent crowding, and may sometimes necessitate the extraction of one tooth and the re-alignment of the others to avoid the loss of several.

DEFECTIVE OPERATIVE AND PROSTHETIC PROCEDURES.

The next group of etiological factors has to do with the operations performed by the dentist for the restoration of lost tooth tissue. Mention has already been made of the damage done by traumatic occlusion through building occlusal surfaces too high or with an inharmonious arrangement of the inclined planes. Remember that the teeth may meet properly in the ordinary closing of the jaws, yet exhibit a marked traumatic occlusion in the movements of mastication. Open or improperly formed contacts have also been mentioned. Much damage is done by placing fillings or crowns without regaining space lost by the teeth tipping together as a result of interproximal decay. This squeezes out the gum tissue from between the roots, making a splendid lodging-place for deposits of tartar, food, and bacteria, and making it impossible for the septal tissue to be

maintained in a state of health. Let me recommend the Perry separator and base-plate gutta-percha here. Edges of crowns need never go farther than half a millimeter under the gum margin unless unusual strength is required.

The usual taper of the root renders it utterly impossible to make a band which will fit any farther up the root than the root-trimming instruments will go—and they seldom go far enough under the gum to be lost to sight. In many mouths the gums will not tolerate the least contact with a band no matter how well fitted. The trimming of gingival margins of fillings without injury to the gum is difficult. It will usually be best accomplished with delicate files, of which several designs are available. Failure to properly restore the shape of labial and lingual surfaces may subject the gum margin to unaccustomed impact of food passing rootwise over these surfaces in mastication. All restorations must have polished surfaces to permit of proper cleaning. It seems to be little appreciated that the gum tissue immediately around a natural tooth is more sensitive to pressure than the gum tissue over the bony ridge where teeth have been extracted. This requires extra grinding of facings and trimming of dentures where they are to rest against these tissues.

TRAUMA.

Trauma, as distinguished from traumatic occlusion, means an injury effected usually from outside the mouth. Extreme and rapid separation, improper use of clamps and ligatures, and blows may do much damage to the periodontal tissues. Improper or excessive use of the toothbrush may do some harm, though usually slight as compared with that produced by insufficient brushing.

ABNORMALITY OF TOOTH SURFACE.

By abnormality of tooth surface we mean a surface which exhibits a roughened or etched enamel, abnormal form, or presence of hard or soft deposits. Rough enamel may be as irritating to

the gum margin as a foreign substance. Abnormal form acts through encouraging the formation of deposits, or permits unnatural impaction of food against the labial or lingual gum margin. Hard deposits are both salivary and serumal calculus. Hard and soft deposits irritate both mechanically and chemically.

ABNORMAL SYSTEMIC CONDITIONS.

Of the secondary etiological factors, we may give some attention to abnormal systemic conditions. These include definite disease conditions such as diabetes, syphilis, etc.; nutritional disturbances; neuroses; conditions of the circulation both general and local.

Most of the etiological factors we have been considering, both primary and secondary, have their opposites or factors favoring health. These may often be so marked as to more than offset pathological factors present, or alter very materially the type of disease. For instance, a patient came to me some years ago with the upper and lower right bicuspid meeting practically edge-to-edge. The buccal cusp of the upper was worn down practically level with the sulcus, evidence that a very marked traumatic occlusion must have existed when the teeth were first erupted. In the average mouth this tooth would have been loose, with decided inflammation, pocket formation, exudation of pus, in short a severe case of pericementoclasia. In this case the tooth was firm and the surrounding tissues normal except for a slight recession on the buccal aspect. The man was a horse-trainer, living out of doors the year round, and had never had a day's illness. The vigor of his constitution and of the periodontal tissues was such that he was able to correct the occlusal trauma by abrasion before the tissues around the tooth gave way under the strain.

VARIOUS TYPES OF PERIODONTOKLASIA.

We shall now take up the various types of periodontoclasia with special reference to the etiological factors concerned in their production. In analyzing the field,

we find five distinct types of periodontal disorders, namely, gingival recession, gingivitis, pericementoclasia, alveoloclasia, and periodontal abscess. Each of these may be subdivided as our knowledge of them is extended. As in the case of the etiological factors, two or more of these disease types are often found in one mouth or around one tooth, yet these cases can always be analyzed and the types differentiated. This is a great aid in diagnosis, since we find that certain causative factors have a tendency to produce certain types of disease. This is a point I cannot emphasize too strongly, and I shall enlarge on it a little later. The name of each disease type indicates the portion of the periodontal tissues chiefly involved, hence careful examination by mouth mirror, blunt explorer, and palpation will determine the type or types present. To those not familiar with this classification it might be pointed out that the distinction between pericementoclasia and alveoloclasia lies in the formation of the typical pocket, pericementoclasia being the type which occurs as a result of the severing of the pericemental fibers. In alveoloclasia the pericementum is not destroyed to the extent that a pocket is formed, but the bone of the alveolus is absorbed, allowing some movement of the tooth in its socket. This type is more common than is generally supposed.

While the etiology of these diseases is so complex as to make it impossible to consider all of the factors which may enter into the causation of each, yet it will be possible, and I hope valuable, to point out the factors most commonly associated in producing these types, remembering always that no one factor is by itself capable of producing periodontal disease.

GINGIVAL RECESSION.

Gingival recession in its pure form consists of a drawing back of the gum tissue coincidently with some absorption of the crest of the alveolus, thus exposing the cementum, but without visible evidence of inflammation or pus formation.

The primary factor is usually trauma—an excessive and improperly directed use of the brush or undue impaction of food on the labial or lingual gum margin. Secondary factors are frail bony support and insufficient local circulation. Traumatic occlusion may be a primary factor especially if resistance to infection is so marked as to prevent pocket formation.

GINGIVITIS.

Gingivitis is an inflammation of the gingival margin, the pathology being similar to that of inflammations in other soft tissues. Primary factors are mechanical irritants such as hard or soft deposits, outstanding edges of fillings or crowns, etched enamel, defective contact, and traumatic occlusion. Secondary factors are sluggish circulation, lowered resistance to infection, bacterial invasion, and nutritional disturbances. These factors if combined with trauma, and in many cases without it, will cause a combined gingivitis and recession with possible pus formation. This combination is characterized by the fact that the recession keeps pace with the severing of pericemental fibers, and thus no pockets are formed. It is thereby differentiated from pericementoclasia. A sub-type of gingivitis is acute ulcerative gingivitis, sometimes called Vincent's infection. It is characterized by sudden onset, severe pain, rapid ulceration of the gum margin, sometimes sufficient to expose the alveolus, and general febrile disturbance. In this type alone do we find bacteria playing very nearly the part of a primary factor. Their attack is, however, always preceded by a chronic gingivitis from tartar, edges of fillings, etc., which may be so mild as to have escaped notice previously. The bacteria are Vincent's spirochete, a streptococcus, and a fusiform bacillus, acting in symbiosis. They form an anaerobic combination, this feature indicating the desirability of an oxidizing treatment. Sodium perborate, a teaspoonful in half a glass of water, gives most satisfactory results, along with careful and thorough scaling and polishing.

PERICEMENTOCLASIA.

Typical pericementoclasia exhibits a severing of the pericemental fibers with corresponding absorption of the bone of the alveolus, but without destruction of the overlying gingival tissues, resulting in the formation of a pocket. It may be complicated with gingivitis or recession, or both. There may or may not be perceptible pus formation. The tooth may or may not be loose. This is the typical so-called pyorrhea alveolaris. The most common primary factor in pure pericementoclasia, and one almost constantly present when the tooth is loose, is traumatic occlusion. Open or defective contacts usually produce a gingivitis as well as a pericementoclasia, but not looseness. Rough margins and deposits of various kinds will be a factor in producing gingivitis, but are not in themselves capable of producing pockets, as stated before. In other words, when your blunt platinoid probe slips into a pocket, look for either traumatic occlusion or open contacts. When a tooth is loose, look for traumatic occlusion. The secondary factors are the same as in gingivitis.

PATHOLOGY OF PERICEMENTOCLASIA.

The pathology of pericementoclasia needs some consideration, and for this purpose we cite a typical case: Let us assume that we find a tooth somewhat loose, with a pocket from which pus can be expressed, slight gingival inflammation, but practically no recession. The train of pathological phenomena starts with an irritation of the pericementum by occlusal trauma, the side on which the pocket will later appear being that which receives the greatest strain. Next we find an active followed by a passive hyperemia in the pericementum. Then comes slight absorption or rarefaction of the bone of the alveolus. Following this we find an exudation of a serous or even of a hemorrhagic nature under the free gum margin, resulting in the deposition of serous calculus at this point. To the occlusal trauma we now find added

the irritation of this serumal deposit, producing a gingivitis which paves the way for bacterial invasion of the gingivæ and pericementum. Pus formation then begins, with bacteriolysis of the pericemental tissue preceded by absorption of the bone of the alveolus. Inflammation continues, with its serumal or hemorrhagic exudate, and consequent progressive formation of serumal calculus.

The points to which attention should be called are, first, the primary traumatic occlusion, and then the secondary part played by the serumal calculus. This calculus, although an active irritant, is not an original cause of the disease, but is in a sense the result of the disease. In other words, we need to look on serumal calculus when encountered in our exploration of a mouth, as a diagnostic sign, a guide-post pointing to some preceding irritant. And our treatment must accordingly be planned so as to remove not only the serumal calculus, but the irritant responsible for its presence. This previous irritant is very commonly a traumatic occlusion, but any of the other primary factors may be responsible.

The point I am driving at is not simply to give a diagnosis of a fully developed case of pericementoclasia, but to indicate the means by which it may be detected in the early stages, so that preventive measures can be applied. In other words, if you find a departure from the normal when examining the soft tissues, look for the primary factors which may be responsible. I have found traumatic occlusion to be so constant a factor in periodontoclasia that I have made it a rule to examine for it whenever I find serumal calculus or even a gingivitis, unless these are very obviously explainable by the presence of salivary calculus, edges of fillings, open contacts, or some other primary cause. It might be well to call attention here to one of the mysteries of the past, the hit-and-miss nature of pericementoclasia, the healthy tooth between two badly diseased teeth or the very loose tooth between two sound ones. This is all cleared up by having the patient close the teeth

and simulate the movements of mastication. The loose teeth will move as contact with their opponents is made, thus demonstrating the traumatic occlusion. So we find that the mystery is no mystery, but the inevitable result of an excessive strain on the supporting tissues of the affected teeth.

ALVEOLOCLASIA.

Alveoloclasia, as stated before, is characterized by absorption of bone, allowing mobility of the tooth, without a severing of the pericemental fibers. It is apt to be accompanied by some recession, but usually not by gingivitis. The primary cause is always a traumatic occlusion. Freedom from deposits and high resistance to infection make bacterial invasion difficult, hence the pericementum is left practically intact, and there is no pocket formation, no exudation of pus.

PERIODONTAL ABSCESS.

Periodontal abscess may be one of three varieties, *i.e.* pericemental abscess occurring in a previously normal pericementum; gingival, discharging through the gingival tissue overlying a previously formed pocket in a case of pericementoclasia; and periapical, ordinarily called alveolar abscess. Since the last-named occurs as a result of root-canal infection, it need not be considered here. The infection in pericemental abscess is usually of hematogenous origin, rather than an invasion from the gum margin, but the primary factor is usually an accidental trauma or traumatic occlusion. Gingival abscess is a sudden "firing up" of a previously established chronic suppuration. The primary factor is of course that of the original disturbance. The formation of this secondary abscess is due to gravity, sluggish circulation from diabetes or some other systemic disorder, or the partial closure of the gingival orifice of the pocket. Abscesses may occur in a gum margin due to presence of a hard material such as food or cement under the gum margin of a tooth on which a band or orthodontia appliance is fitted.

RESPONSIBILITY OF THE GENERAL PRACTITIONER IN PERIODONTAL DISEASE.

Before summing up, let us consider for a moment the responsibility of the dental profession in the department of periodontal disease. You will agree with me, I think, when I say that he who represents himself to be a practitioner of dentistry is morally and legally bound to provide for his patients the benefits which the current state of knowledge of the dental art puts within their reach. If a considerable number of dentists are able to prevent and cure dental periodontal disease, and if the methods of preventing it are within the grasp of the general practitioner, then the responsibility for the loss of teeth whose value cannot be measured in dollars and cents rests squarely on his shoulders. Abscesses due to root-canal infection are making it necessary, and will probably continue to make it necessary, to extract many teeth in which disease has obtained a foothold, due often to legitimate causes affecting the health of the pulp. But the legitimate loss of teeth through periodontal disease is very rare, providing the patient consults his dentist at regular intervals and takes proper care of his mouth. There are two reasons for this—periodontoclasia *can* be cured, and still more important, it *can* be prevented—and, as usual, prevention is easier than cure. Dentists who are specializing in this field are able to check gingivitis, eliminate infection and pus formation, make loose teeth firm, in many cases cause the overlying gingival tissue to form a vital attachment to the cementum, and, moreover, to bring about a new growth of the bone destroyed by the previously existing disease condition. This constitutes a cure, since it restores the parts to health and functioning power, closes up pus pockets, and, in a word, restores the periodontal tissues to essentially their original condition. The specialist and also the general practitioner can with even greater certainty perform a still more valuable service, namely the prevention of these disorders, or what amounts to

the same thing, the cure of incipient cases.

To prevent or cure necessitates a knowledge of the conditions involved, their etiology and pathology. Application of this knowledge, or diagnosis, requires first a training in the detection of periodontal disorders in their earliest perceptible stages, even more than in the advanced conditions. This may be most effectually accomplished by the use of a chart on which provision is made for the recording of conditions of the soft as well as the hard tissues, and the etiological factors present. Examination of the soft tissues necessitates the use of an instrument not often found in the dental office, a soft blunt explorer of platinoid or silver of about No. 26 gage. This instrument can be slipped under the gum margin to detect pockets and their approximate depth, without causing any injury or much pain. Since all surfaces which have lost any pericementum need surgical treatment, it is not necessary to use a tempered explorer to detect tartar, especially as the scaler properly used will give much more accurate information of that nature.

In making examinations we should be ever on the watch for traumatic occlusion. Inflammations and deposits of serumal calculus which are unevenly distributed about the mouth or which are not readily explainable by other factors, will point to this arch evildoer, as will all loose teeth.

In treatment it should be remembered that the relief of traumatic occlusion must be carried to a point where the affected tooth may have rest. If grinding is done it must be continued until the articulating paper will barely mark the tooth, and the tooth itself does not move in any of the movements of mastication—unless, of course, grinding is contra-indicated by some other condition. Spaces between teeth should always be closed, even if not apparently doing any harm when first noticed. The harm will come in the course of time.

Root surgery, or scaling so called, must be perfect to secure results. In other

words, failure to stop pus and inflammation does not mean that the disease is of systemic origin, that standby of the past, but that root surgery or the relief of some primary factor has been incomplete.

A vigorous circulation of blood in the gums is one of the essential barriers to disease. It is obtained by vigorous and properly directed use of the tooth brush, by vigorous mastication, and by properly given prophylactic treatment with the orange-wood stick. Better a little recession from over-brushing than stagnation and débris from under-brushing.

It should be remembered that the usual "cleaning" of the teeth by the dentist will not prevent caries or periodontoclasia. Learn to know how a prophylactic treatment differs from a cleaning,

and then teach this distinction to your patients.

In closing, let me remind you that there is nothing supernatural in nature. Every event has its cause; mysteries are mysteries only until the relation of cause and effect is determined. So in regard to this subject: The causation of periodontoclasia once determined is as logical as any geometrical problem. And since we find that the causes in practically all cases are under our control, we cannot truthfully take refuge in the old saying that "Pyorrhea cannot be cured," but must shoulder our responsibility and do to our patients as we would be done by.

437 FRANKLIN ST.

[See also *Discussion*, as reported under "Proceedings of Societies," this issue.]

When Shall Root-canals be Filled, and How?

By ARTHUR BARTON CRANE, D.D.S., Washington, D. C.

(Read before the Maryland State Dental Association, Baltimore, June 5-7, 1918.)

THE leaders of the medical profession are waiting with open minds for conclusive evidence that periapical infection can be eliminated by treatment through the root-canal. Meanwhile, knowing full well that extraction and thorough curettage will be followed by a healthy condition of the tissues, it is small wonder that many physicians are demanding such treatment for all infected teeth. This attitude will continue and increase until some tangible method of proving the effectiveness of root-canal treatment is available.

The present dependence upon radiographic check, while reasonably convincing in some cases, requires from three to six months for demonstration. In cases attended with serious metastatic lesions this interval may be sufficient,

if periapical infection persists, to so increase the malady that all chances of recovery are lost. This method, further, is controvertible on the ground that evidence exists that new bone-growth may take place in the presence of dangerous infection. Even eliminating these objections, the check-up method is inefficient because of the disinclination of dentists and patients alike to make use of it. Hence, if we are to have a method of proving the elimination of periapical infection which will be universally valuable, it must be applicable prior to the filling of the root-canal.

Since the necessity for completely filling all canals has become an accepted policy, methods have been advanced and instruments have been invented by which this can be accomplished, in most cases,

to a reasonable certainty. The time has come, it having been demonstrated that the mechanical difficulties can be overcome, to give more widespread consideration to the manner of determining when sterilization has been accomplished. Until the sterility of the tissues can be reduced to demonstration, the filling of root-canals remains an empirical procedure, worthy of the condemnation it is receiving in many quarters. A study of culture methods and culture media is the foundation upon which must be builded any attempt to predetermine the possibility of success in this operation.

CULTURE METHODS FOR DETERMINING STERILITY OF ROOT-CANALS.

The first difficulty to present is that of obtaining a reliable material for the culture. The finding of a negative result may only mean that the material has been gathered from a part of the field temporarily under the influence of antiseptics, or that enough of the antiseptic remaining in the canal has been carried over to inhibit bacterial growth. The finding of a positive culture may be the result of contamination.

For about two years the writer has taken cultures from practically every tooth treated, the method being to dry the canal with cotton points, absorbing any excess of antiseptic present, and then passing a sterile apexographer through the canal until pain is experienced. As the instrument is withdrawn it is made to scrape the side walls of the canal, and then used to inoculate the media.

For the purpose of checking the value of this technique the following experiment was made: In fourteen cases sterile cotton points were immersed in a sterile 25 per cent. solution of glycerin and sealed into the canals with gutta-percha rendered sterile in the flame. Four days or longer were allowed to elapse, dependence being placed upon the hygroscopic action of the glycerin to induce osmosis, and thus draw into the cotton the fluids in the dentin and periapical region. At the following sitting the cotton points were removed with sterile

forceps and dropped into the culture tubes. Immediately thereafter a culture was taken with the apexographer as described. Considerable difficulty in preventing contamination of the cotton was experienced, as in most instances it stuck to the forceps or to the side of the culture tube and had to be released with another instrument. However, allowing for this contamination, which did occur in four cases, as shown by the growth of spore-forming bacilli, the results were the same in all cases save one. When one tube was negative, the other also was negative; when one was positive, the identical organism developed in the other. The one exception was a case in which the tube inoculated with the apexographer developed a streptococcus growth, while the tube inoculated with the cotton grew a spore-forming bacillus only.

As a further test of the usefulness of the apexographer method, another series of six cases was tried, this time using glucose broth to saturate the cotton points, thus furnishing a rich pabulum for the propagation of any vital bacteria within the field. This experiment resulted in a similar coincidence of results, with one exception, in which a streptococcus grew in the cotton tube, while the apexographer tube remained negative.

If these experiments prove anything, they establish the apexographer method of taking the culture as reasonably dependable.

While it is possible that some more efficient method of taking the culture may be developed, with such an easy means now at our command there is no present justification for an empirical acceptance of unreliable clinical evidence in determining when a canal is ready for filling. While it cannot be refuted that the finding of a negative result by this method is not always an absolute assurance of sterility, yet the finding of a positive result is a sure indication that sterilization has not been accomplished, and by this guide alone we shall be prevented from filling the canals of many infected teeth which would otherwise seem to justify that procedure. For those who have not taken the routine

caution of making cultures prior to root-canal filling a surprise is in store, for streptococcus growths will be recovered from about 30 per cent. of all cases which give every clinical indication of successful termination of the treatment.

Next in difficulty only to obtaining the culture is the selection of a practical culture medium. At the beginning the writer used an agar slant, which was inoculated with a stab and a smear. The slowness with which growth was developed led to the opinion that a sufficient amount of antiseptic must have been carried over with the culture material to cause inhibition of bacterial growth. It was therefore decided to use liquid culture media, and in such volume as to dilute this inadvertent antiseptic to a neutral state. Glucose broth, Besredka's egg broth, and glucose broth enriched with human ascitic fluid, have all been tried and compared.

As in the overwhelming majority of cases we have to deal with the streptococcus, some medium especially acceptable to its growth must be selected. The uncertainty of growth in glucose broth soon caused us to discard it. The ascitic fluid media undoubtedly gives a large percentage of growths, but the difficulty of obtaining and keeping it in a sterile condition makes it rather impracticable for the average dentist. Careful comparative tests have been made with the egg medium which demonstrate its prompt efficiency in growing all strains of streptococci, and this medium is easier to make and keep.

The length of time allowed before pronouncing a negative result is also of importance. With the ascitic fluid medium we had one case which developed a streptococcus growth on the thirteenth day, and with the egg medium one which developed on the eighth day. With these exceptions, however, we have had no growths developed in either of the above media after the third day, so that is now being used as the minimum time for culture.

Thus far I have tried to impress the importance of some test for sterility before filling the canal. This practice is

not expected to appeal to those who blindly attempt to treat all infected teeth, nor to those who advise extraction in every case. Fortunately for the conservative dentist there lies a mid-course in which such precaution will lead toward success. Antiseptics will not work magic, and whatever their virtues they are only a means to an end, which is the elimination of the infection.

It is my belief that if there is any present means of accomplishing this, it lies in the use of electrolytic medication, combined with dressings of the mildest antiseptic oils during the intervals between treatments. The use of powerful antiseptics of escharotic character has been relegated to the mistakes of the past, while the filling of the canal with so-called permanent antiseptics is a fallacy so transparent as to require no time for discussion.

SELECTION OF TEETH IN WHICH THE ROOT-CANALS MAY BE SUCCESSFULLY FILLED.

It may as well be acknowledged that there are many infected teeth which cannot be saved; but a selection of risks, through careful diagnosis, makes a favorable prognosis reasonably safe in many cases.

For the sake of convenience, pulpless teeth which are rarely benefited by antiseptic treatment may be classified in three groups, as follows:

Group I: *Teeth having considerable dead apical cementum.*

Group II: *Teeth having considerable dead alveolar cementum.*

Group III: *Teeth having their apical openings within the maxillary sinus.* (Fig. 1.)

A careful consideration of the features of these three groups may have a tendency to prevent many unsuccessful attempts at tooth treatment.

GROUP I.

This group consists of "Teeth having considerable dead apical cementum."

(Fig. 2.) After one has extracted a number of badly infected teeth and curetted the periapical bone, or better still, has cut down upon periapical lesions for root resections, it requires an intense faith in the potency of antiseptics to believe that this infected field, full of dead and dying

FIG. 1.

Types unfavorable for canal medication: I. Too much dead apical cementum. II. Too much dead alveolar cementum (pyorrhea). III. Canal opening within the antrum.

tissue, can be restored to health by treatment through the canal. That certain infected teeth are rendered safe by such treatment is past dispute, hence any method of foretelling which teeth give promise of recovery is of value. With this in mind I proposed, about a year

FIG. 2.

ago, a system of classifying periapical disease by radiographic study. Your indulgence is asked for a reconsideration of this plan.

In dealing with periapical disease we are confronted by three distinct conditions, easily recognized in the film, which may be differentiated as follows: Class No. 1: Circumscribed radiolucent areas.

Class No. 2: Diffuse radiolucent areas. Class No. 3: Circumscribed radioparent areas. (Fig. 3.) Let us examine each of these classes in turn.

(1) *Circumscribed radiolucent areas.* These may vary from a slight thickening of the apical pericementum to a considerable rarefying osteitis. No matter to what degree the tissues are affected, however, to fall into class 1 the film must show a circumscribed area with the line of demarcation between radiolucent and normal bone indistinct. (Fig. 4.) This class represents the primary results of infection, and the affected area is circumscribed, because the vital forces,

FIG. 3.

1. Circumscribed radiolucent area (granuloma). 2. Diffuse radiolucent area (granuloma). 3. Circumscribed radioparent area (dental cyst).

while being slowly overcome by the invading organisms, are as it were making an orderly retreat. It often happens at this stage that proper root-canal treatment so attenuates the invading organisms that the balance of power passes to the tissues and a cure results.

(2) *Diffuse radiolucent areas.* The irregularity of outline may vary from a simple break in limitation to an entire loss of regular form. The line of demarcation between normal and radiolucent bone is even less distinct than in class 1. (Fig. 5.) This appearance in the film is produced by ramifications of granulation tissue, which extend from the central mass into the surrounding bone. Wherever this abnormal tissue comes in

contact with bone or cementum, disintegration of the hard tissue takes place; the cementum becomes roughened, and the bone becomes softened. Teeth of this class represent the effect of neglect or of improper treatment of class 1 cases, and while they sometimes respond to treatment, the ascendancy of the infection is so pronounced that it is seldom that teeth of this class are restored to health, except by root resection.

(3) *Circumscribed radioparent areas.* In this class the film shows an intensely dark area surrounding the root-apex and this area in turn is surrounded by a dense

Dental cysts are frequently a late sequel of devitalization of the pulp from traumatism, but unless infection is introduced into the canal by the invasion of decay, or by the injudicious attempt of an overzealous dentist to treat the tooth, they may increase to the size of an English walnut, and still, to the best of my knowledge, remain sterile. On the other hand there is good evidence that in certain cases these cysts may form about class 1 infections of low virility, thus to a certain extent limiting their danger. Whether infected or not, such apical conditions are probably never eradicated

FIG. 4.

(Class 1.)

FIG. 5.

(Class 2.)

FIG. 6.

(Class 3.)

white line, which definitely separates the radioparent area from the normal bone. (Fig. 6.) Such a picture is always indicative of the formation of a cyst, which is nature's method of protecting the organism from the baneful effects of certain noxious irritants. Hartzell in a recent paper states that these cysts are always the result of infection and that they are always infected. While my own opportunity for investigation has been extremely limited as compared with his, I am emboldened to disagree with him by the fact that repeated attempts to get growths from the fluid in cysts attached to the roots of teeth with unbroken enamel covering the crown have met with failure, and this result cannot be entirely disparaged by criticism of the culture methods or culture media.

by treatment through the canal. The cyst wall, which lines the dense layer of bone, indicated by the white line in the radiograph, must be entirely destroyed or the cyst will be re-formed.

To return to the subject of the selection of risks, it will be seen that most cases in class 2 (Fig. 5) and all cases in class 3 (Fig. 6) have so much denuded apical cementum that the attempt at treatment through the canal by any of the methods now in vogue is a doubtful procedure. Such teeth, therefore, are included in group I.

GROUP II.

In the second group are "Teeth having considerable dead alveolar cementum." (Fig. 7.) This includes all pulpless

teeth having pyorrhea to the extent of pocket formation. In such cases there is generally a pathway of drainage established from the periapical area to the gingival margin, which can often be

FIG. 7.

traced out in the radiograph. Attempts to sterilize such teeth invite failure, as constant reinfection will take place.

GROUP III.

Here are placed "Teeth having their apical openings within the maxillary sinus." When the pathfinder is passed through the apical foramen in certain upper bicuspid and molars, there is a twinge of pain after which the instrument moves upward without resistance or pain. This is an indication that the antrum of Highmore has been invaded. The radiographic film is of little use in confirming this point. It is probable in most cases of this character that an infected granulation tissue has been substituted for the normal lining membrane of the antrum about the root-apex. Prognosis in this event is most unfavorable, as reinfection is almost certain to occur.

We are confronted, then, by the prospect that the only teeth which offer opportunity for a favorable prognosis are those in class 1, periapical disease, a very few in class 2, and those in which the periapical conditions are still normal. Even when we thus limit our field of endeavor we are given but little encouragement by the studies of Price and

Brooks, but, in the light of the almost universal failure of our past performances, these possibilities should be given serious consideration. The faint-hearted may become discouraged, but our professional duty to our patients is to face the facts and restrict our treatment to those cases where successful termination is within the bounds of reason. Then when an auspicious result is indicated by a bacteriological test, the root-canal may be filled, with a clear conscience.

EXTENT TO WHICH CANALS SHOULD BE FILLED.

Provided the root-canal has been properly prepared to a conical form, the filling operation is not one of great difficulty, but it is necessary that some judgment should be used as to the limitation of the filling. The desire of conscientious men to surely fill the canal to the end has led in many instances to grotesque overfilling, which at best serves no useful purpose.

The amount of filling material, if any, which shall be forced through the apical

FIG. 8.

opening depends on the extent to which the cementum has been denuded of its life-giving membrane. (Fig. 8.) In some cases of class 1, and cases where there is as yet no periapical destruction, the line of the pericementum, as disclosed by the radiograph, is continuous. In such teeth, to be ideal the filling should stop at the apical extremity of the canal. (Fig. 9.) It may be wise to here again call atten-

tion to the fact that most canals terminate in a crater-like depression in the cementum. For the purpose of root-filling this should be considered as an integral part of the canal. The radiographic evidence of a perfect filling in such event will indicate a little ball at the root-apex. (Fig. 10.)

Wherever denuded apical cementum exists, the attempt should be made to cover this with a cap-like film of chloro-percha (Fig. 11), but in no event is it necessary or even desirable to project a solid gutta-percha point beyond the root-

for which purpose, only, the latter is used. A somewhat larger cone is now selected, but not so large as to impinge on the canal walls in its passage to the apex. If the apical foramen has been enlarged it is usually better to cut off the extreme point of the cone. The cone so selected and prepared is dipped in resin varnish and is slowly insinuated through the canal almost to the end.

At this stage time must be allowed for the chloroform to be dissipated before progressing with the operation. This will be caused partially by evaporation

FIG. 9.

FIG. 10.

FIG. 11.

end. A careful study of the radiograph will indicate the amount of filling material which will be of benefit beyond the canal proper (Fig. 8), and by different methods of inserting the filling this amount can be controlled to a reasonable degree.

THE TECHNIQUE OF ROOT-CANAL FILLING.

If the requirements call for a filling confined to the canal, the technique is as follows: The canal, enlarged and shaped to a conical form, is flooded with a chloro-resin varnish, somewhat thicker than that recommended by Callahan. A fine cone is introduced and passed toward but not quite to the root-end, and dissolved by a stirring, *not* a pumping motion. This will coat the canal walls with chloro-percha, which will be extra-adhesive on account of the mixture of resin,

and partially by combination with the gutta-percha of the cone, so that as the chloro-percha becomes thicker the cone becomes softer, until the whole mass in the apical third of the canal is of about the same consistence. When the gutta-percha at the coronal orifice is as plastic as unvulcanized rubber, a blunt plugger, too large to go far into the canal, is slightly warmed and used to gently pack the filling material toward the apex. At the first suggestion of pain the packing should cease. A fine plugger which will pass freely into the canal is now warmed and carefully passed through the center of the filling until it reaches the apical third of the canal. It is then moved about in such a manner as to pack the filling material against the side walls, after which the deficiency thus caused is filled with a suitable gutta-percha cone, packed to place.

If the radiograph shows the filling to be incomplete, this can be corrected, at a subsequent sitting, by placing a drop of chloroform in the pulp chamber and passing a root-pick through the filling toward the apex until pain is experienced, and then packing a cone in the opening thus made.

The tendency however, is to overfill rather than underfill the canal. This can be guarded against, first, by the stirring motion in making the chloro-percha, which should be limited to an amount sufficient to coat the walls only; secondly, by inserting the prepared cone in such a manner as not to force the chloro-percha ahead of it, and thirdly, by patiently waiting for the whole mass in the farther end of the canal to become homogeneous.

In the majority of cases, fortunately, because it is more easily managed, the filling material should pass beyond the canal to cap the denuded root-end. Depending upon the amount required for this purpose, the canal should be lined or even filled with chloro-percha in the manner already described, only now the cone should be dissolved with a pumping motion, as many cones being thus used as may be necessary to furnish a suitable amount of this semi-fluid substance. A cone is then selected which will approximately fit the canal. This is dipped in chloro-resin and gently pumped through the chloro-percha to the end of the canal. During these pumping operations there will often be slight twinges of pain, but these are caused by the irritation of the chloroform and must be disregarded. When the cone finally appears to have reached the end of the canal, time must be allowed for the chloroform to diffuse, but not so long as when it is desired to confine the filling to the canal. Usually, when the blunt end of the cone is somewhat plastic, if pressure is brought to bear the point will not be solid enough to penetrate tissue, but will pass through the apical opening at such consistence as to distend the granulation tissue and flow in the direction of least resistance, or in other words, fill the space where tissue is missing. It is possible that the natural elasticity of the granulation tissue will

have a tendency to force this gummy mass back toward the denuded cementum. This may be further assisted by making pressure on the crown of the tooth with the finger, or better, by allowing the patient to bite hard with the tooth on an ordinary lead-pencil eraser.

The amount of filling material passed through the apical opening may be controlled, first, by the amount of chloro-percha formed in the canal; second, by the gradation of the pumping motion in dissolving the cones, and third, by the consistence of the mass when pressure is exerted. If too soft the chloro-percha will run off into the tissue. If enough time has not been allowed for the tip of

FIG. 12.

Filling in mesial root caps a large denuded area of apical cementum. Filling in distal root projected by too precipitate pressure forcing the chloro-percha ahead by its piston-like action.

the cone to soften, this will pass through and penetrate the tissues, often forcing the chloro-percha ahead of it by its piston-like action. (Fig. 12.) By studying the foregoing features I believe that it will be possible to so perfect this technique that practically a predetermined amount of gutta-percha can be extruded, and that in most cases it can be confined to the immediate utility of capping the root-apex.

My knowledge of the adhesion of such cappings is limited to two cases where the teeth were extracted several months after the insertion of the fillings. In both instances the cap was very adherent to the cementum and as hard as vulcanized rubber.

From what has been said it is evident that the present status of root-canal work is not all that could be desired, but the writer has cast his lot with those who

insist upon sifting this question to the end before becoming either over-optimistic or discouraged. It is possible that, after all, the effort of dentistry to find a means by which badly infected teeth can be restored to health may result in failure, but this is no reason for weakly surrendering the endeavor. Rather, with scientific impartiality let us continue the investigation of this problem until we arrive at the truth.

Meanwhile, it is likely that an increasing number of pulpless teeth will be condemned to the forceps, and that the apparently retrogressive plea of Broomell for the dévitalization of the pulps of sound teeth will appear more and more rational. For many years the dental profession ignorantly destroyed normal pulps in order to make bridge abutments more secure. The disclosures by the dental radiograph of the periapical conditions which supervened gave the profession such a shock that now the conscientious dentist looks with fear and trembling upon the necessity for such an operation. And yet, until some more satisfactory abutment for vital teeth is devised, the demand of an educated public for removable bridge-work will continue to make pulp devitalization necessary.

In view of the holocaust wrought by this agency in the past, how may it now be undertaken with safety? The crux of the whole matter lies in asepsis. Provided the pulp may be extirpated and the canal obliterated without introducing infection, no untoward result should follow. As in any surgical operation of choice, the prime consideration is the selection of cases in which conditions will not forestall a happy termination. Teeth with deep-seated decay, pyorrhea, or in close proximity to periapical areas of infection should be avoided, and preference should be given to teeth with unbroken enamel covering.

ASEPTIC PRECAUTIONS IN PULP DEVITALIZATION.

As a prerequisite to an aseptic operation, all instruments needed should be placed in an alcohol bath at least three

minutes before being used. The operating table should be covered with a thick sterile towel, handled with sterile forceps. Napkins, small cotton sponges, cotton points, and smooth broaches wrapped with cotton, should then be taken from their wrappings with similar care and laid upon the towel, one of the napkins being used to cover the other dressings. To be acceptable it is essential that these must have been subjected to sterilization in the autoclave and kept securely wrapped until the last moment.

The tooth selected is isolated by the rubber dam, being certain that no possibility of leakage of saliva exists. The tooth or teeth in the field should now be rubbed with dry cotton or gauze to remove the mucus, after which the whole field, including the teeth, with dam and clamp, if any, is painted with tincture of iodine. After the iodine has dried it may be washed off with alcohol to lighten the field.

The exploratory opening is made with a small sharp round bur just taken from its alcohol bath with sterile forceps. When the pulp chamber is discovered a larger bur is substituted, so that direct access may be had to all canals. This step should be carried forward in a calculating manner, as it corresponds to making the primary incision in any other surgical operation. The object here is the safety of the root, and as much of the crown should be sacrificed as may be necessary to prevent the possibility of failure.

The pulp having been freely exposed, all débris is cleaned away with alcohol. A fine smooth broach is used to explore the canal, the pulp extirpated, and the canal enlarged. Repeated washings with hydrogen dioxid, using the cotton points or cotton-wrapped broaches as swabs, will remove all the blood and débris and leave the canal walls clean. The canal is then dried with cotton points, and as a super-precaution against the possibility of infection having been introduced, electrolytic medication may be used to the constant of 30 as recommended by Prinz.

A strand of picture-wire, wrapped with cotton and placed in apinol prior to the operation, is now passed into the canal

and sealed there with gutta-percha rendered sterile in the flame. A radiograph is made and studied as a guide to the length of the canal. No attempt should be made to fill the canal while anesthesia persists, otherwise there will be an almost unpreventable tendency to overfill the canal, which in this instance could surely accomplish no good purpose.

The gutta-percha points used should be dipped in tincture of iodine and allowed to dry. After being washed in alcohol they should be kept in alcohol in a suitable container. Just before the filling operation they are removed from this bath with sterile forceps and placed upon one of the sterile napkins to dry.

The anesthesia most satisfactory for this work is obtained by slow subperiosteal injections of cocaine immediately over the root-end. Pressure anesthesia is contra-indicated, and conductive anesthesia is not complete in all cases.

In closing this paper I desire to acknowledge my indebtedness to Drs. Kinyoun and LeComte of Washington for their many valuable suggestions and earnest co-operation in the study of culture methods and culture media as referred to herein.

The Next Quarter Century in Dentistry :

A Prophecy Based on the Needs of the Profession and on Our Hopes
for Its Development.

By W. D. TRACY, D.D.S., New York, N. Y.

(Read before the Dental Society of the State of New York, Saratoga Springs,
June 13-15, 1918.)

THE rapid evolution of dentistry as a profession from the establishment of the first dental college at Baltimore in 1839 to the present day has been stable and full of interest from every point of view.

Medicine, always jealous of her prerogatives, and justly so, did not welcome, nor did she assist in the birth of dentistry, but on the contrary, was quite antagonistic to the foundation of a dental college, and those far-seeing and courageous pioneers, Harris and Hayden, in spite of rebuff and discouragement had to fight the early battles of professional dentistry unaided by their medical *confrères*.

The fact that the broad gulf of preju-

dice and even of distrust that used to separate medicine and dentistry has been steadily growing more narrow indicates a splendid progress on both sides. It shows that the master minds in dentistry have realized the necessity of giving dental students the broadest possible medical foundation for their dental education. It shows that medical men have awakened to the fact that teeth are really a part of the human economy. They have grown into a realization that the teeth in health and disease bear the same relation to the body as do other organs.

Coincidentally the dental profession has been made to realize most keenly the fact that in dealing with the teeth and diseases of the oral cavity they are assum-

ing the same responsibilities as does the surgeon who operates on other parts of the body.

DENTAL EDUCATION.

In 1839 there was one dental college which graduated two men, and now at the end of seventy-nine years there are 47 dental colleges and schools of dentistry in the United States. The time necessary to acquire the dental degree has lengthened from a course of a few months to the present requirement of four years.

In the early years of dentistry the successful man could skilfully encompass all branches of the work, whereas today the field of dentistry has become so broad and embraces so much that no man can become expert in all departments, and the profession is naturally dividing up into specialties.

The materials used and the methods and theories of practice have almost all undergone radical development and radical changes as the penetrating light of science has illuminated the pathway of dental progress.

The wonderful growth of the profession since its birth impresses upon us the great possibilities of its future expansion. With the impetus it has already gained it is only natural to believe that its further development will be even more rapid, and that the scope of dentistry and its use and value to humanity will be materially enhanced with each succeeding year, until one day it will be one of the most important, if not *the* most important, special field of work in the practice of medicine.

For mere man to prophesy what developments will take place in dentistry in the next twenty-five years were vain; but basing our reasoning on the remarkable growth of the past, it may be interesting at least to set down our present impressions concerning what may take place in the future.

That the institutions of dental learning are the very foundation of the profession and of its future development is a truism. It is safe to prophesy that the requirements for entrance to these insti-

tutions will be increased from time to time as the curriculum itself becomes more taxing on the mind of the student, because the individual not provided with a good fundamental education and not well grounded in the habit of study will be unable and mentally unqualified to encompass the work provided by the curriculum.

It is quite possible that many of us may live to see the day when matriculants will be entered as dental students only when they have finished a four-year collegiate course, and by the same token a quarter of a century may not have elapsed before all graduates in dentistry must first have obtained an M.D. degree.

In this connection the following quotation from Professor Edwin T. Darby, who for forty-one years has been an active and potent factor in dental education, will be of interest. He says: "It is my opinion that the day is not far distant when the student of dentistry will graduate as an M.D.; but one degree will be conferred, and that will be Doctor of Medicine. And it should be so. The dental student must now spend four years to prepare himself to practice one branch of the healing art, and the medical student spends no more time, and is granted a degree which permits him to practice all branches included in the medical course. The medical and dental professions are gradually coming nearer together, and the gap between them is so slight that in time it will be closed, and the relations between the man who practices medicine and the man who practices dental surgery will be of the most intimate kind—and it should be so, for reasons which need not be mentioned."

PREVENTIVE DENTISTRY.

The dental mind has for many years been applied to the study of prevention of dental diseases, and with certain limitations preventive dentistry is an accomplished fact in the present day.

The systematic prophylactic treatment of children and youthful patients, as well

as of adults with restored or cured cases, has proved its value as a preventive measure, and it is now an established part of the work in every well-regulated dental practice.

What has seemed to be the most overwhelming problem faced by the dental profession is the care of the teeth of the millions of school children in this country. The economic waste and the actual cash loss due to ill health and mental deficiency caused solely by dental disease and defects in all large municipalities is too well recognized to need reiteration.

While preventive dentistry is applicable to patients of all ages, its most important field of usefulness is perhaps in its application to the school children, and in several sections of the United States the systematic prophylactic treatment of public school children has been carried on with the most salutary results. Preventive dentistry as applied to the school children of our country is really in its infancy, but the present indications warrant the prophecy that during the next twenty-five years the development in this special field of work will be so great that every school in the country will be obliged by law to provide prophylactic treatment by properly trained dental hygienists for the children under its control.

It is quite possible that in isolated sections where the population is scattered, rural automobile dental clinics will make their periodical rounds under state control to minister to the dental needs of the school children and others who cannot go to the larger towns for treatment. This plan has already been initiated in Vermont, and possibly in other states.

In view of the important work done by Dr. Alfred C. Fones of Bridgeport in making preventive dentistry in the schools of his city a reality, and because of his years of study on this and allied problems, his opinion is worthy of record and is quoted as follows: "It is much easier to prophesy the result that may be attained in preventive dentistry in a quarter of a century than to attempt to outline the probable stages through which it will pass in securing that ultimate result. The efforts of our

profession will be concentrated upon the prevention of dental caries and pericemental infection from the gingival border. The two great factors that will control these diseases are proper food and prophylaxis."

The dentist will become an educator instructing his patients in matters of diet conducive to normal mouth conditions and bodily health. His greatest field for service will be among the mothers of small children, who will learn of the practical elimination of free sugars, white breads, crackers, etc., and that the substitution of simple, wholesome, hard foods will help to produce the ideal arch development and reduce the tendency to dental diseases. The beginning of this education of the public as to proper foods is made practical, even at the present time, by the war situation, which has forcibly eliminated the use of a good part of the free sugars and white breads from the diet. Until this slow educational campaign has made itself felt, the most rigid system of prophylaxis and habitual daily mouth cleanliness must be carried out to overcome the evils of our present form of diet.

The medical profession, as well as the general public, is slowly realizing the great importance of sound teeth and healthy mouths to general health, and this knowledge will become so widespread that a National Department of Health, of which dentistry will be a very important part, will be created to help produce and maintain health. The value of prevention over cure is already realized to such an extent that every health activity is being carried on along lines that tend to prevent disease.

The National Department of Health with its own secretarial bureau will find it within its power to compel scientific feeding and care of the body by enforcing the pure food laws and restricting the manufacture of candies, confectionery, etc. The necessity for this restriction is made apparent by the statistics secured in the examination of thousands of months of men drafted into the national army. These show that the Italians, with a national consumption of

but thirteen pounds of sugar per capita per annum, have teeth in which dental caries is the exception rather than the rule, in contrast to the mouths of the boys of America, whose average consumption of free sugar is about ninety pounds per capita per annum.

It is my belief that the great educational and preventive work will be carried on by an immense corps of dental hygienists in public schools, hospitals, and other public and private institutions, aside from those employed in private practice. The educational and preventive dental clinic for public schools will be universally adopted, and although municipalities may conduct reparative dental clinics, they will be separated and apart from the school buildings. In 1943 fully 30 per cent. of the school children will be free from dental caries, and many of the diseases of childhood will have been stamped out. A toothache will be generally understood as a calamity, as it will usually mean pulp involvement, and for the masses this will mean extraction. Focal infections of the teeth will have long since been acknowledged as an important source of systemic infections, and the dental practitioner will be obliged to be a medically educated man in order that he may have a greater knowledge and broader vision of dentistry, which will be recognized as the most important specialty of medicine.

In spite of all the preventive dentistry that can be accomplished during the next twenty-five years, the profession at large will still be constantly occupied with curative and reparative work in the mouths of people who did not come under the influence of compulsory dentistry as children, or who were personally neglectful of their mouths and teeth after reaching adolescence.

We naturally ask, "What will be considered good practice twenty-five years hence in dealing with a tooth in which the pulp has lost its vitality or which suffers an exposure of the pulp through the removal of deep-seated caries?"

The idealist would say that if all the plans advocated by the champions of preventive dentistry could be put into effect

at once and carried out systematically through the next quarter century, there would be no exposed pulps, and therefore no problem in connection with devitalized or infected teeth.

FOCAL INFECTION.

The dental millennium, however, will not be reached so soon, and pulpless and infected teeth will still be among the problems with which the busy practitioner will have to deal. Cases of this kind will occur much less frequently in the future, of course, than they do today, and just what the attitude of the profession will be toward the cases of fresh pulp devitalization and cases of putrescent pulp is a matter of some conjecture.

Opinions on this point are many and varied. Some of our most careful thinkers and men of conservative speech have been heard to say that within five years no tooth with any form of pulp involvement would be permitted to remain in the human mouth, the ground for this assertion being the assumption that a pulpless tooth must necessarily be an infected tooth even though the vital pulp were removed under modern aseptic methods and the canals were thoroughly opened, sterilized, and filled according to the accepted procedure of the present day.

We have sufficient light upon the relation that focal infections about the mouth and teeth bear to the general health, to make us realize the danger of retaining teeth so infected. But, to offset the pessimistic view quoted in the previous paragraph, there are others who are equally thoughtful and conservative and whose wide experience entitles them to speak with some authority, who feel that the tooth from which a freshly devitalized pulp is removed can be treated and filled in such a manner as to be safely retained as a healthy and useful dental organ, and the writer of this prophecy is a supporter of this latter view.

While we admit that the prevention of dental caries and other diseases of

the teeth is the shining goal toward which the profession is working, we must acknowledge also that our much-talked-of scientific development falls far short of our ambitions if we are unable to so treat teeth with freshly devitalized pulps that they may be safely retained.

BRIDGE WORK.

There can be no doubt concerning the ruthless devitalization of dental pulps in sound teeth for the purpose of anchoring fixed or other types of bridge work to them. This practice, which has been accepted by many as being in the best interests of the patient, will be abandoned in time, and ways of supplying the missing natural teeth will be devised which will not necessitate devitalization.

Fixed bridge work will be used less and less as the rank and file of the dental profession become awakened to its inherent defects and devastating influences, and there will be a renaissance of the removable denture.

In regard to possible changes which may take place in the methods of filling teeth between now and 1970, it may be said that there is nothing in sight on the dental horizon at the moment which indicates any marked change or radical improvement in methods of filling teeth.

SILICATE CEMENTS.

In 1890 Dr. Ottolengui wrote a sort of prophetic story which appeared in the *Dental Review* for January of that year, the theme of which was "Dentistry in the Year 2000." Among other interesting things in this story it was related that in 1970 a man named Erickson had produced and presented at one of the international conventions a plastic filling material which could be softened by low heat and placed into the cavity as we would insert gutta-percha. When set, this material was as hard as tooth structure and would permanently retain a high polish. It was obtainable in all shades so that teeth could be very perfectly matched.

If we could be assured of having such

a material for our use, many of us would be glad to stay around until 1970 to have the pleasure of using it! No one dares say that we may not have a perfect universal filling material supplied for our use even before 1970, but certainly it has not yet been presented to us.

While we have welcomed the silicate cements of various names and used them in the various parts of the mouth, we have had it borne in upon us repeatedly that even the best of these materials cannot be classed strictly as permanent fillings—neither can the silicate cement filling be universally used on all surfaces of the teeth. In other words, they are fillings limited in their field of usefulness and in their period of durability; but until we find some better material we shall continue to use these silicate cements in a certain class of cavities.

THE GOLD INLAY.

Bearing on this subject and upon the gold inlay and the foil filling, Dr. Darby's comment is again interesting and illuminating. He says, "I predict that the dental profession will soon return to the use of gold foil for filling cavities of moderate size. We have learned that the silicate cements are not lasting. The fillings that have lasted twenty-five and fifty years have been made of gold foil or other forms of gold and have been placed in the cavity by laborious effort, and for that reason, among others, the profession has been quite willing to fall away from its use. It is true that gold has serious objections, such for instance as its inharmonious color and the labor incident to its placement in the cavity, but it has so many advantages over the plastics, that I predict that its use will become more general. The gold inlay has undoubtedly come to stay, but in small cavities on occlusal surfaces foil fillings are better. All silicate preparations must be regarded as temporary, and were it not for the esthetic quality they possess they would soon become less and less used by the dentist who has for his object the permanent quality of his operation."

While there are at present several special fields of work in dentistry, it is prophesied that, within the next few years, specialization will be even more marked than it is today, and that men having special interest in or special skill in a certain line of work will devote themselves exclusively to that department and will be known as specialists.

Organized dentistry represented by its various local and state societies and by the National Dental Association is bound to become stronger with the passage of time, and next to the institutions of dental learning it will be the most potent factor in the elevation of dental standards. The only changes that are anticipated in the dental societies during the period supposed to be covered by this prophecy are those which will incidentally occur in increasing the efficiency of these organizations and rendering them as democratic in their administration as possible.

ARMY DENTISTRY.

The need for more dentists in the United States army is so palpable that it would seem almost impossible for the Congress to fail in its duty in this matter, and it is prophesied that in 1943 there will be at least four dentists for every thousand men.

The conditions which make it difficult to enact national laws regulating the practice of dentistry uniformly in the several states will undoubtedly change with the passage of time, and it is prophesied that ultimately there will be a Federal law which will control and regulate the practice of dentistry throughout

the country. It appears to the writer that such control is simply a matter of educational development, and that the benefits of national regulation would be numerous and quite obvious.

While the growth of dentistry has been very rapid and far-reaching in its effect, and on the whole satisfactory to those most interested, what can we say of the mental attitude of the rank and file of men who make up the profession, and from whom we have so often heard the clamorous call for professional recognition equal to that given to our brothers in the practice of medicine?

Have they grown along with the profession itself, or have they clung to a rather narrow range of vision and retained a too materialistic attitude? As dentistry has grown, and as its importance as a factor in the health of the nation has been recognized and acclaimed, has the dentist become more professional in his habit of thought and in his relations with the people of the community in which he lives? Has the spirit of service and the feeling of altruism penetrated to his heart, and has he shown by his relations with humanity that he is the true professional gentleman which he wishes the world to believe him to be?

These questions will not and should not be answered here, but the writer, with all the optimism that he naturally feels in connection with the development of dentistry, ventures the prophecy that within twenty-five years there will be many expressions of professional feeling that are not in evidence today.

The Needs of Prosthetic Dentistry.

By NORMAN S. ESSIG, D.D.S., Philadelphia, Pa.

(Read before the Maryland State Dental Association, Baltimore, June 5-7, 1918.)

PROSTHETIC dentistry combines engineering and art in very subtle proportions, and, as is the case in every other instance where either of these is employed, much preliminary study is required before the first or fundamental steps can be taken.

If the dental profession is not willing to spend as much time as is necessary to accomplish the best results possible in prosthesis, they have not the best interest of their patients at heart, and should not therefore undertake that particular kind of dental service.

If we are not willing to spend as much time as is necessary in the preliminary steps, our patients will require us to do so in the final adjustment or in the reconstruction of the work.

In presenting the subject of the selection of artificial teeth and the harmony produced thereby, I have endeavored to effect a rather radical transposition, and to depart from present methods as far as the old principles will allow, without disturbing the fundamental sequence of events.

In other words, the attempt has been to place the selection of artificial teeth, and their manipulation, both before and after their adjustment in the human mouth, as nearly as possible on the same basis as the natural teeth in their evolution and development of form and arrangement in the human skull. Consequently, the formula for the method employed to bring about results of the greatest value should follow along and compare to the true scientific and physiological laws in order to produce results, by artificial means, commensurate with those obtained by the processes of nature.

In other words, a synthetic form and outline is obtained bearing a direct relation to the combination of basal types, but maintaining its greatest relation or resemblance to one of these, which we shall call the base.

Like any other creative process, however, there must be a basis of operation upon which the structure is to be built, and which is to form the basis of subsequent calculations. This is also true of the natural development and eruption of the natural organs of mastication. It would therefore be most logical to ask ourselves the question, Upon what does Nature base her system, and what physiological process obtains in the normal human being with regard to dentition?

We find that the capsule from which the human teeth are formed develops, matures, and pushes itself into place governed and limited by the surrounding bony walls within which this development takes place, and that the size and shape of the fully developed tooth and its final alignment is dependent largely upon the space allotted to it and the influence exerted by cusp formation; this is especially true in the case of the lateral incisors, which are more than likely to bear little relation to the type represented by the centrals.

Even a superficial summary of a part of Nature's method will more than account for the fact that the human teeth are a law unto themselves, though this digression eventually becomes almost rhythmical in method and recurrence.

THREE BASAL TYPES OF TEETH.

It has been found as a result of systematic research that the teeth of man

owe their present form to the blending of three primal or basal types, which in their purity conform to the rectangular, pyramidal, and rhomboid, and which may be found throughout the world regardless of race or environment.

Having taken these points into consideration, let us see how we may apply just these conditions to the formation of porcelain teeth.

In the selection of porcelain teeth for an artificial denture, especially in the case of edentulous persons, much time must be spent in the contemplation and analysis of the face. No man can quickly scan the face of his patient, and conclude at a glance just what type and arrangement is indicated. Therefore, any method which holds out such ideas is misleading to say the least.

Anyone who has been deprived of the natural organs of mastication for any length of time has generally worn artificial substitutes, and it is therefore always advisable that a consultation appointment should be given with the idea of studying the face and noting the requirements of the case, in order that a readjustment or a harmony be re-established which will blend the arrangement of the artificial teeth with the lines of the face, so that attention will not be attracted to the fact that there has been a dental service.

It is undoubtedly true that often it is desirable or that a face demands a blending of the basal types to produce the required harmony; it is also true, alas! that this fact in many instances is either not recognized or is disregarded altogether in the selection and adaptation of porcelain teeth.

We may conclude that if we ourselves are to produce appropriate blendings as a result of the study of any given face, we can do so to a much better advantage by starting the procedure with a strong and pure type of tooth, and specializing a modification to suit the case. This is only what has taken place in the original condition, and many times what we regard as a harmonious condition is but a countenance whose identity has become established by reason of the natural ar-

range of the teeth and the effect they have on the face and its expression. Therefore, while we must not neglect the individual tooth and its anatomic variations, we must regard the six anterior teeth as a unit. This is how Nature has been able to use any of the three types whenever she pleases, and produce harmony.

These variations from the harmonious and symmetrical are what may be designated as "harmonious discords," and can only be recognized by the establishment of the bilateral symmetry accomplished by the comparison of the two halves of the face between certain established lines. Therefore, that portion of the face which is most characteristic, and at the same time nearest to the teeth themselves, should be selected, because this area is less affected by high-light, shadow, style of wearing the hair, etc. The discordant element which enters into the question must be applied after harmony has been recognized.

For this reason the area I have established for my convenience is from the eyebrows to the commissure of the mouth, with the median line vertically through the nose and at right angles with the horizontal lines, which are parallel to each other.*

It should be borne in mind that what we often select as an example of harmonious discord, or an individuality, is but the result of a digression from the symmetrical and ideal, and the effect that such a condition must necessarily have on facial expression, and therefore, if possible, it is our function to restore this unusual or characteristic individuality, and, like all reproductions of nature, it is an art of the highest type.

If it is not possible to restore the mouth to what it was originally, we may serve the patient and do ourselves credit by restoring the organs of mastication in an alignment of the teeth similar to that which is in the mouth of someone else, providing we do not distort or disfigure the lines of the face by so doing.

* See "Type vs. Temperament," etc., DENTAL COSMOS, vol. lix, 1917, p. 1110.

The patient will have to get accustomed to an unusual condition in any event, so that our efforts should be directed along artistic lines, and the conventional regular alignment should be discarded.

I should like at this point to revert to what I said regarding digressions from the harmonious. This particular phase of the subject sometimes becomes almost a local or sectional characteristic, and proclaims at times the part of the country from whence a person comes. This is amply exemplified in those coming from the north of Ireland, where a peculiar wedge-shaped arch and overshot appearance is more than common. This peculiarity may embody any of the true types.

The two central teeth, which may be said to establish the type indicated, should be in conformity with the portion of the face confined within the lines indicated above; and not only should the outlines suggested by this method be adhered to, but modifications of profile of the teeth should also be made to conform them to the general contour of the face.

VARIATION IN LATERAL TEETH.

A very logical explanation for the great variation in the lateral tooth, and the fact that in many instances that tooth does not maintain the type of the central teeth, is that in its developmental stage the room allotted to the capsule is often curtailed by reason of the robust character of the central incisors and the cuspids; so that it might, therefore, be said of this tooth that a part of its function is to fill the space between its more vigorous neighbors, and also to blend or harmonize the lines of these dissimilar teeth, whose form and function is widely different.

There is, of course, a typical lateral to be found in well-developed dentures which is an ideal companion to the truest type of central, where development has been ideal and uniform. Harmony, however, is not marred by the insertion of almost any type of lateral whose width is appropriate, and individuality is often obtained by modifying the lateral incisor to suit the case in hand.

The cuspid or canine tooth is a most important one, and great character, or a lack of it, can be produced by the appropriate placement of these teeth, which no doubt have more than one function to perform, apart from the fact that they have their use in the preparation of food, or, as in the lower animals, as a weapon of offense or defense. The canine is also a great stabilizer, and by reason of its strong roots acts to reinforce the arch at a point where the roots of the adjoining teeth are widely different. Therefore, in maintaining the sequence of events and the ideas around which these methods have been established, a typical and robust form should be adopted, so that modifications at any point may be made, and the harmonious draping of the anterior teeth maintained and completed.

Heretofore we have been in the habit of filling a given space by selecting six anterior teeth with appropriate bicuspsids and molars to suit the case. As a matter of fact, artistic effect is greatly increased by selecting the two central incisors separately with a view to type, and two cuspids which shall denote character. After having aligned them on the arch a modified lateral whose proportions are governed entirely by the space left for it is placed in position, because by so doing we have only done what nature does.

Inasmuch as artificial teeth of porcelain are the means by which we reproduce the natural organs of mastication which are designed and arranged by an all-wise Creator, whose plan, though it has been modified by man through his failure to observe certain laws, we would do well to follow, in this sequence and plan, in the system by which we select and arrange our porcelain substitutes, because we have to restore a condition the responsibility for which must ever remain with that Supreme Designer whose method will forever obtain, and whose wisdom we may not dispute.

Reverting to the discordant elements which must evolve in the process herein described, it might be well to dwell upon the phase of prosthesis a little more in detail.

We have said that harmony should first be established; this is true according to our formula, and is verified by the examination of crania which show clearly the natural, physiological process. Orthodontists claim that there is a method of calculation which will produce the normal arch and alignment in each case that presents itself. This would lead us to believe that nature established a harmony, and then departed therefrom. Let us therefore do the same. Let us select the teeth with a view to a certain distortion later which shall conform to the irregularities which confront us. We therefore select the types we desire from any of the three basal forms, and consequently regard the face of our patient with the view to distorting the form and alignment of the teeth selected, so as to produce a harmony of line and contour in keeping with the face, regardless of how irregular it may be.

We must determine whether we wish to produce an appropriate degree of age and wear by cutting the tooth at the incisal edge, by exposing the neck, or by a compromise of both. It is only in rare instances that there is not considerable elongation in elderly persons, and unless there is a marked overbite, occlusal wear is manifest to a greater or less degree. Approximal wear, while not so apparent, is generally evident upon close examination of those fifty years of age or older.

The foregoing may be classed among the discordant elements in the process by which we will endeavor to keep pace with nature.

USE OF THE ARTICULATOR.

The use of the articulator will be of great service, providing our instrument reproduces and maintains the movements established by the mandible and is one that is capable of producing an occlusal wear by persistent attrition like that which occurs in the mouth, and which is limited and influenced by the habits and physical capabilities of the individual.

These movements are controlled also

by the bicuspid and molars and the radius of action permitted them by their cusp formation and general alignment, which either allows or precludes clearance laterally.

It will be noticed, when we examine a mouth having good articulation, that wherever a tooth has a marked projection in cusp formation, a compensation for that prominence is made in its antagonist by an indentation, or a semi-approximal surface which is shared in good proportion by the two opposing teeth, forming little occlusal planes which are separated by the triangular ridges typical in bicuspid. It is just as much a part of our plan to follow nature at this point as at any other; therefore, we must again reproduce nature by making our masticating teeth also a reproduction of nature, with all the proportions to the smallest detail of their formation.

Reproductions of this kind in porcelain produce the most wonderful results, and such teeth are free from the interlocking feature which is most objectionable to the majority of patients. They also have a slight inter-occlusal space due to cusp formation, within which food may be held in small quantities without keeping the jaws apart during mastication. This feature allows the patient to thoroughly masticate, not merely to mash or bruise the food.

Great stress should be laid upon the fact that the one dependable and anatomical articulator is the combination of the upper and lower jaws of the patient. Inasmuch as great variation of form of the bony structure of the human head obtains in the human race, the individual, as he presents himself to us for a service, furnishes us with our only true guide to the correct relation of that particular mandible and maxilla. The articulator must therefore be only an instrument to maintain movement and relation in the absence of the patient.

The jaws of an edentulous person have no path or track upon which to functionate or guide them in mastication, as is the case with those who have teeth, and while it is possible for anyone to get accustomed to an inferior form

of denture, and in time get some degree of service therefrom, our plain duty is to come as close to the natural state as we can by following nature's method in the creation and development of the organs of mastication, and the manner in

which they are placed in the mouth in the human species.

1700 LOCUST ST.

[See also *Discussion*, as reported under "Proceedings of Societies," this issue.]

Anaphylaxis in Connection with Asthma, Hay Fever, and Various Skin Diseases.

By J. A. TURNBULL, M.D., Boston, Mass.

(Read before the Connecticut State Dental Association, New Haven, April 18-20, 1918.)

ANAPHYLAXIS is the opposite condition from Phylaxis, or protection. It describes that peculiar train of symptoms which certain poisons exhibit, of increasing instead of diminishing the sensitivity of an organism to their action.

In anaphylaxis the chemical condition of the blood is altered by absorption of certain substances foreign to it, or a quantitative increase or diminution of some particular substance which has a right to be there. The action of the blood on the wall of the bloodvessels or nerve apparatus of the bloodvessels, or on the heart, is attended by an alteration of the vasomotor system; the substances which produce the changes are proteins or their derivatives, and are known as antigens; this gives rise to production of anti-bodies.

Vaughan* says, "All proteins contain a poisonous group which is identical or closely similar in action; this poison is a cleavage product, acid in reaction, capable of forming compounds and reacting much like globulins in its behavior to neutral salts."

All proteins, whether of animal or vegetable origin, possess anaphylactic properties for those individuals to whom they are sensitive.

Protein sensitization may be either (1) hereditary or (2) acquired. The hereditary form may be transmitted from the maternal or paternal side to the offspring, passing through several generations, or we may have omission in a number of generations, the sensitization later making its appearance in the offspring. It may show the same conditions in each of various forms of disturbances in different parts of the body in different individuals; that is, one individual of the family may have frequent head colds, another seasonal hay fever, due to pollen, or we may have two or more members of a family with seasonal hay fever, one of the spring, another of the fall type, while another may have both vernal and autumnal types; other members of the family may be troubled with disturbances of the lower respiratory tract, bronchial asthma and bronchitis. These may be seasonal and caused by the various pollens which produce hay fever.

In those hay-fever cases in which asthma occurs with the attacks, the asthma usually develops in the latter part of hay-fever season, and may continue for some time after the usual pollen period. This is due to the patient being saturated with the pollen protein, and to bacteria which the patient may be sensitized to during the attacks of hay

* Vaughan, *Journ. A. M. A.*, November 25, 1916.

fever, and to some food protein, as the pollen disappears which lessens the entrance of this protein. As gradual elimination goes on the attacks of asthma usually subside, but there are some in which attacks continue. These may be relieved by avoiding foods to which the patient is sensitive, or else by the use of a sensitive bacterial protein.

Acquired protein sensitization may be produced by injection of foreign protein, or through the influence of some inter-current disease or infection, as has been done with animals—namely, by injection of albumen in rabbits; after ten days they are not able to tolerate the same or a much smaller dose.

An engineer, age thirty-five, while at college under severe strain, received an infection of the hand and arm from which he was confined to the bed for several weeks. After recovery from the infection the patient noticed, at frequent intervals, outbreaks of urticaria; on testing, reaction to pork and grapes was found, also to staphylococcus pyogenes aureus.

Protein skin tests are made, whenever practicable, on the flexor surface of the forearm. If this surface is not suitable from some skin condition, as eczema, I use anterior surface of arm, extensor surface of forearm, anterior surface of thigh, back, or abdomen. The flexor surface of the forearm is preferable, as it is not so hypersensitive as the other areas.

For the tests, a sharp narrow-pointed scalpel, alcohol 70 per cent., gauze, solution of KOH $\frac{1}{2}$ of 1 per cent., and medicine dropper, are necessary.

The forearm is washed with alcohol, dried, and the area cleansed and covered with gauze. At a point 3 cm. below the bend of the elbow place a drop of the KOH solution with the dropper; through this moisture make an incision $\frac{1}{8}$ cm. in length just through the skin, being careful to avoid drawing blood. This will act as our control. Below this point (2.5 cm.), near the external border, place a drop, and continue placing drops across the arm at intervals of 2.5 cm. To the first drop add a small amount of protein to be tested. Mix with the scalpel and avoid irritating the skin.

When the protein dissolves, make incision, through the solution, in the skin as with control, continuing the same process with the other drops down the arm. Reactions take place in from two to twenty minutes, and comparisons are made with control. Reactions show by redness, wheal, or wheal and redness. After thirty minutes the protein is washed off, and the reactions read and recorded.

Proteins causing disturbances may enter through (1) respiratory tract, (2) gastro-intestinal tract, or (3) action of bacterial proteins from absorption of some focus or foci. We may have more than one source of entrance of the sensitive protein, namely, (1) respiratory and gastro-intestinal tract, (2) respiratory and focal infection, (3) respiratory, gastro-intestinal, and focal infection.

There are a few sensitizations which show skin reaction, and produce symptoms by only one protein. Practically all cases show multiple sensitizations, that is, reactions to more than one protein. These proteins may have a closely related chemical combination, or a component part which is nearly identical in all of that class. As in case of one sensitive to vertebrate fish, there may be some protein with a factor common to a number of that species.

In patients sensitive to food proteins, omission of these foods from the diet is followed by relief of asthma and other anaphylactic disturbances. Another method is to omit the food from the diet and desensitize the patient to that particular food by giving small doses subcutaneously and gradually increasing the dose, avoiding too great a local reaction. Desensitization to foods is successful in many cases, though there are some we are unable to desensitize. Treatment with protein reduces the skin reaction, and sufficient treatment renders the skin test negative to that protein.

Patients with asthma attribute attacks to dust, odors, smoke, dampness, cold air, east winds, changeable weather, menstruation, exertion, excitement, indigestion, nervousness, and cold. These are all secondary factors, acting on a sensitive respiratory tract which has been

excited and rendered irritable by a sensitive protein. After removal of the cause and suitable treatment, these factors fail to produce attacks and the intestinal disturbances are relieved.

Hay-fever cases, due to the pollen of willow, alder, oak, birch, maple, apple, chestnut, grasses, rose, ragweed, golden-rod, cockle-bur, sunflower, can all be treated with pollen protein to which the patient is sensitive.

There are asthmas brought about by the inhalation of the protein of horse dandruff, dog, cat, rabbit, and guinea-pig dandruff, chicken feathers, and from various birds and fur-bearing animals. We can treat these by avoiding such inhalation: for instance, in case of sensitiveness to feathers of the pillow, by elimination of the feather pillow.

Blacksmith, age twenty-six: was subject to attacks of asthma, brought on when near a horse or driving a horse. If a small amount of horse's perspiration touched the patient's skin, within five minutes there would be redness and wheals. This case was treated with horse dandruff protein, so that he could be around horses without any attacks of asthma.

Superintendent of bakery, age forty-eight: began working at sixteen in a bakery. At eighteen years of age, when working with flour, he would be subject to attacks of sneezing, watery nasal discharge, lacrimation, itching of eyes, ears, nose, and throat. These attacks increased in frequency and severity for ten years. Then he would have attacks of asthma, which occurred at intervals and increased in frequency and severity. When forty-three years of age he could only work part of the day in the bakery. At forty-six, on entering the bakery, there would almost instantly be brought on severe attacks of asthma. This case gave positive reaction to wheat, rice, and corn; negative to oat, barley, and rye. By omitting wheat, rice, and corn from his diet he could work in the bakery without being subject to attacks of asthma. In this case sensitive protein entered through both the respiratory and gastro-intestinal tract. By omitting these articles from the diet the system was able to take care of the amount entering through the respiratory tract.

Oil dealer, age forty-six: suffered from asthma for three years. Reaction positive to wheat, negative to rye, oats, corn, and rice. Omitted wheat from diet, and in two weeks reported he felt better than for three years;

no attacks. Two weeks later, no attacks. Following this for two days he ate six slices of wheat bread, which brought on the worst attack he had ever experienced.

Housewife, age forty-five; asthma for twenty years. Skin test made, and all the proteins that gave positive reaction were eliminated. After being free from asthma for three months, the patient was instructed to eat plenty of lamb, which gave positive reaction on testing. One lamb chop was eaten, and six hours after she had an attack of sneezing, watery nasal discharge, itching eyes, ears, nose, and throat continually for two hours. Frequent attacks for the next two hours. Forty-eight hours later two lamb chops were taken, and in six hours she experienced severe attacks of asthma lasting two hours, followed by frequent attacks of sneezing, with watery nasal discharge for eight hours; twenty hours later eczema appeared over the entire body. Avoiding lamb soon cleared up the condition. This case was later given lamb protein, subcutaneously, at weekly intervals, beginning with a small dose and gradually increasing the dose according to local reaction, until she was desensitized to lamb, giving no skin reaction. Since then she has been able to eat lamb without any disturbance.

Female, age five; at two months of age eczema all over the body, which continued to her present age. The skin was indurated, thickened, scaly and rough. The smallest amount of egg in the mouth caused immediate swelling of the tongue and the mucous membranes of the mouth and lips. Beef broth made the eczema worse. When at the seashore, if she should go near fish there would occur acute exacerbation of eczema. The patient gave positive reaction to wheat, egg, beef, haddock, and mackerel. These foods were eliminated from her diet and she was desensitized with wheat protein, and later with egg and beef. The skin became soft with very few scales, and resumed normal texture. The patient is now able to eat wheat, egg, and beef.

Female, age twenty-eight: has always known that some of the vertebrate fish, such as haddock, cod, mackerel, and salmon, would produce attacks of sneezing, nasal discharge, dry sore-throat, redness and swelling of the face. Within the last five years halibut and fillet of sole produced the same symptoms. This lady, on eating any of the fish, knows that these symptoms will occur in one hour.

All are aware of disturbances caused by strawberries and tomatoes with some individuals.

In bacterial protein sensitization we can use the same skin test with the different bacterial proteins to determine which is the sensitive protein. No pains must be spared in searching for and removing every disease focus which serves as a focus of protein absorption. More than one avenue may serve as a source of absorption. The focus or foci may be found in the nose or accessory sinuses, tonsils, gums, teeth roots, gall-bladder, and appendix. After these foci are cleared one may have a chronic bronchitis, which can be cleared up by treatment with sensitive bacterial protein.

Female, age forty-two; eczema about the face and back of ears for six months. Test gave reaction to staphylococcus pyogenes aureus. I advised an X-ray of teeth, which showed abscesses at the roots of the upper left

second molar. The tooth was extracted, the abscess cavities cleaned, and in ten days the eczema disappeared.

I have seen a few cases of cancrum oris patients which gave positive skin reactions to some foods. On avoiding these foods there was relief from the cankers. These are the cases which, when the dentist has attended to the teeth, are followed by severe outbreaks of cankers, for which the dentist is severely criticized by patient and friends, and in which he is accused of being unduly rough, or of using unclean instruments, while he is no doubt innocent, the contributing factor being present within the patients themselves, and ready for an explosion on the slightest provocation.

[See also *Discussion*, as reported under "Proceedings of Societies," this issue.]

Dental Clinics in Manila.

By LOUIS OTTOFY, D.D.S., M.D., Manila, P. I.

[SIXTH REPORT.]

PREVIOUS reports of these clinics have been made as follows: DENTAL COSMOS, August 1910, October 1911, November 1912, May 1914, and July 1915.

The clinic at the Philippine General Hospital, which I succeeded in establishing in August 1912, has assumed large proportions. This clinic is now operated as the clinic for the School of Dentistry of the University of the Philippines, of which I am the director. The school was opened in 1915, and we adopted then the regular four-year course, hence our first graduates will receive their degrees in April 1919. At present the school has twenty-five dental students, and the classes will number about forty for the academic year of 1918-19. As the number of students increases and a larger

number perform their practical work in the clinic, the higher class of work will increase. For the present, as is seen by the report, the largest amount of the service consists of emergency cases, that is, treatments and extractions.

Since the establishment of the clinic at the Philippine General Hospital (which is a public institution), the one at St. Paul's, the first one I founded thirteen years ago, has not been as active as in former years, but is still satisfactorily serving the poor in that section of Manila known as the "Walled City."

The clinic at Bilibid Prison, which I opened in 1906, was until lately supplied by my assistant from the St. Paul clinic, but recently the prison authorities have established a more regular and constant service, of which I have no record; hence

the dental work done in the prison far exceeds that shown in this report.

The largest gain in dental service since my last report was made in the public schools. In former years I maintained an irregular service in one of the schools, which could not be made permanent and efficient. Three years ago, I succeeded, with the aid of the then Secretary of the Interior, the Hon. Winfried T. Denison, in having a law enacted creating the Board of Dental Hygiene, which was authorized to collect funds for the purpose of establishing dental clinics in the public schools. It was much easier to get the law passed than to get the funds. Still, I was able to collect enough to open one clinic in the Meisic primary school, with over 3000 pupils—probably the largest single unit of a primary school anywhere to be found—which has been very successful, and is now established on a permanent and solid foundation, having been recognized as a necessity to such an extent that it now receives the financial support of the city.

In connection with that school I have also established a toothbrush drill. This was made possible through the generosity of the Florence Manufacturing Company, donating toothbrushes, and the Colgate Company, which donated tooth paste. During the past year only one hundred pupils, fifty each of boys and girls, have been admitted to the class. All of them are eager to enter it. The drill takes place every morning during a recess, and the improvement in the health and general demeanor of the children, and their application to the work of the schoolroom, has been so marked that the teachers of these pupils have noticed it and commented on it. I hope with the beginning of the coming school year to greatly increase the work in this direction.

Being unable to continue the clinic through the Board of Dental Hygiene, which depended on the uncertainty of begging money and aid (made more difficult on account of the needs of the great war), I succeeded in interesting the school authorities in the matter, with the result that the clinic will be continued by the city schools, and in July

one dentist will be added. I have also seen by the report of the Director of Education that the appointment of a dentist in each province is recommended, and this, no doubt, in course of time, will take place.

Familiar with the various plans recommended for the conduct of dental clinics in public schools, I was in some doubt which policy to adopt. I have reached the conclusion that the preservative service—entailing hopeless expense—unless it could be made universal is of comparatively limited value; second, that the emergency service, coupled with the instruction, is of considerable value. Previous to the establishment of the clinic, in the fifty-odd rooms of this one school, there were from three to five pupils in each room at the very moment suffering with toothache (this, of course, is exclusive of those who remained at home on account of the same trouble). This means that from 150 to 250 children were at school in a condition of inefficiency, causing loss of time to the teacher, loss to the student, and loss to the citizen whose money supports the schools. This has all been remedied, and, by giving an opportunity for the children to get immediate relief, it has increased the attendance at the school. This service I consider to be highly valuable.

By the use of local anesthesia, I have encouraged my assistant to follow up the extraction of diseased roots and unsalvageable teeth as much as possible, being satisfied that while the dental service is meager, this line of work probably yields the most in good results. The record shows that one-fifth of all the service consists of extractions.

But working along on a small scale—filling a few cavities while thousands of new ones are forming, extracting a small number of disease-breeding stumps and teeth while hundreds of others are rapidly passing into the same stage—sometimes makes one feel discouraged, when it is known that, were the means at hand, such an immense service for the general good could be accomplished. I am therefore, as a result of practical experience and observation, deeply convinced of the great value of prophylaxis

DENTAL OPERATIONS PERFORMED IN THE VARIOUS DENTAL CLINICS OF MANILA, P. I., FROM
MAY 1, 1905, TO DECEMBER 31, 1917.

(Under the charge and supervision of LOUIS OTTOFY, D.D.S., M.D., Manila.)

—prevention rather than cure. This is so convincingly illustrated in the tooth-brush drill that it is impossible to escape conviction. The thoroughness in cleaning the teeth; the steady, dogged regularity, finally not only cleanses the teeth, but improves the diseased condition of the gums, and indeed retards the production about teeth and roots which should either be cured or removed.

In the "other institutions" listed in the accompanying table are included pupils in private eleemosynary institutions, such as St. Luke's Hospital free clinic for the poor, Girls' Orphanage, School for the Deaf and Blind, and Home of the Holy Child. In these the service is purely temporary.

The total in these various institutions now foots up over 75,000 distinct dental operations, performed for nearly 30,000 patients, of whom one-third consists of females and two-thirds of males, while all but about 500 were Filipinos.

Aside from the actual results of the operation of these clinics, it is gratifying for me to note the extension and influence of this propaganda. I am certain that its extension in the schools has been made secure. Recently a large commercial firm, an employer of considerable labor, has made arrangements for dental service for its employees. Several years ago I brought this to the attention of one of our largest tobacco concerns, placing the argument on a basis of sanitation—that is, that it is possibly injurious to have operatives about the weed whose breath is germ-laden. Had I the time, no doubt this matter would be seriously taken up by owners of factories and employers of labor. With the exception of the dental clinic at the Philippine General Hospital for which compensation is included in my service for the university, this work all has to be done without remuneration, and it is too much for anyone to do, hence I am gradually passing on the work to someone who will be paid for it, as is now the case in the public schools.

Recently, the Philippine Constabulary, which is our insular police, also created

five positions for dentists; but they have been appointed with too low a grade, that is, only second lieutenant, and difficulty has been found in filling the posts thus created. I think it is contemplated to increase the rank, and of course the pay. The Philippine National Guard also has a dental corps, modeled somewhat after the same corps in the United States army, or rather, as it was a few years ago. It provides for the appointment of one dentist to every 1000 of the enlistment, with the grade of first lieutenant. I have been commissioned a captain in the medical corps, and assigned to organize, instruct, and supervise the dental corps, somewhat like Major Logan in the medical corps of the United States army. These are signs of permanent progress for the dental profession in the Philippines.

We have been made to feel the effects of the war in the increase of the prices of dental goods and supplies, due largely to the decreased shipping facilities on the Pacific. This has unfortunately resulted in a large influx of goods of Japanese manufacture. Efficient as they are in many lines, the Japanese have not improved in the manufacture of dental goods over what they were nearly twenty years ago, when I lived and practiced dentistry in Japan and knew their goods very well. There is too much energy lost in making imitations of and copying outwardly goods of American manufacture, and so far they are expert—but it ends there! Still, for want of American goods we have been compelled to purchase these imitations for some of the clinics on which I have reported in this paper. I have just been informed that the Japanese intend putting two grades of goods on the market—an inferior product, that is to say the present product, and a superior product which is to command a higher price.

We feel assured that the recently opened dental depot of Mr. Louis Xiques, formerly of the S. S. White Company's branch in Buenos Aires, will greatly improve our present most deplorable service.

Some Experiences in the Camps and Fields of the Armies Overseas.

By Major CLEMENT A. PENROSE, U. S. Army Medical Corps.

(Read before the annual meeting of the Maryland State Dental Association, Baltimore, June 5, 1918.)

GENTLEMEN OF THE MARYLAND DENTAL ASSOCIATION:

I AM not a sob speaker; I shall not try to harrow you with German atrocities, undoubted facts as they are, or with the mangled bodies of the dead and wounded, etc.; I feel that my mission is a broader one. I wish to tell you something about our trip abroad, what we saw and what we learned in the British camps and fields—to stimulate you to a deeper sympathy for our own flesh and blood across the seas; to help cement, if only in a small way, the ever-growing feeling of brother for brother, the unity in thought and purpose of the Anglo-Saxon race, allied with our martyred friends, the French people, on whose blood-soaked soil, it seems, the final outcome of this great war must eventually be decided.

I have recently returned from the front, and I want to go on record to the effect that I have returned from England with the greatest love and admiration for the Englishman. I was detailed by the Surgeon-general of the United States to go to England to visit the army camps in England, then to cross over to the army front of the English, and there to study the conditions in the fighting zone. I was then switched to the American forces, and by accident, not by design, I happened to be in a little army camp hospital where the casualties of our American troops were treated. I personally had the experience of treating surgically the first American wounded of this great war.

We left New York harbor, August 23, 1917, on the good ship *Baltic*, with some two thousand troops, a hundred or more nurses, Red Cross workers, etc., on board. We had the usual lifeboat drills, and lights out at night, about which you have probably heard, and which gave an atmosphere of suppressed excitement throughout the journey. We finally reached a large harbor where we were joined by twelve other good-sized vessels. After being detained here some days we left as a fleet, and all proceeded toward the shores of England. When about three days out we were met in the early morning by a number of little craft, eight torpedo boats (English) and three destroyers (American). I can never forget the beautiful sight these little vessels made in the light of a glorious sunrise, coming over the edge of the horizon like a swarm of hornets, with their business-like riggings and armament. How we welcomed them! knowing that the question now of an efficient convoy through the submarine danger zones was well solved. Ten of our vessels proceeded toward France with eight torpedo boats, while the three *White Star* liners, the *Belgic*, the *Megantic*, and our ship the *Baltic*, proceeded directly to Liverpool, each convoyed by an American destroyer. In a few hours we had all separated and soon lost sight of one another. All went well with us until about one hundred miles out from the Irish coast. We were at dinner in the first-class dining-room, eating a very excellent dessert. I remember, when suddenly a tremendous crash

was experienced on the port (or left side) of the Baltic, near which my table was placed. The cry arose, "We are hit!" and immediately five blasts of the steamer's whistle were sounded, the signal to assemble at our lifeboat stations on the decks. Some of us organized the exit of the first-class passengers from the dining-room; the nurses behaved splendidly. The men stood aside and waited for the women to go out first. This was done in an orderly, I might say an American manner. We took our places near our respective lifeboats, and these were quickly lowered to the water's edge, and waited patiently, occasionally looking over the side of the vessel to see if we were sinking or careening, as we imagined would soon be evident. In the offing, about one-third of a mile away, those standing on the port decks could see a dense smoke screen beyond which our gallant little destroyer was rapidly moving back and forth. After a half-hour or so the first officer with his crew came around and said, "The danger is past. You are all dismissed." Wondering what had caused the crash, I looked up my good friend the ship's doctor, who told me we had experienced simply the concussion from a depth bomb which our gallant little destroyer had sent down over the submarine, and that he had every reason to believe that the submarine had been destroyed. This belief was confirmed later by the Admiralty reports which we read in London.

We arrived in London during that harvest-moon time in which some of the worst air raids, from the standpoint of mortality, took place, six in succession, and others with an occasional day or two intervening. This is a wonderful experience. A thousand anti-aircraft guns go off at once. The heavens are mapped out like a checker-board, and certain areas in the sky are filled with bursting shrapnel, the effort being to drive some of the planes into these danger zones; very few, however, are destroyed in this manner, the main effect being that the airplanes are kept so high in the air that they cannot make out any important

landmarks. Thus far none of the beautiful old historic buildings in London have been damaged. The way the British public accepts these raids is magnificent. It is considered bad form to pay much attention to them. The servants can go home, or into the tubes, if they so desire, but the householders seldom leave, and go about their usual routine without showing any fear.

Unfortunately the mortality has been quite high among the non-combatants, especially women and children. To date, I understand, England has lost probably, through submarines and air raids, more than fourteen thousand people. One day when we were coming up from Folkestone, we were told that, just the day before, a bomb was dropped on a primary school-house in midday and from twenty-five to thirty little children were mangled.

I did not ride in a single automobile in England or in the war zone in France that was not driven by a woman chauffeur. In one case I was riding with an officer in an automobile, and he said the chauffeur of the automobile was his colonel's daughter, enlisted like a man and drawing a private's pay.

In economy, England has made a great advance in her camps, both at home and in the field; in many the garbage is ground up, even the bones, and all fat is extracted by superheated steam; the residue is pressed into cakes for dog-biscuits or hog-food, and occasionally mixed in fodder for cattle. The wash-water from the dishes, etc., is passed into a common gully outside the kitchens and into three tanks of cold water, from which the grease is skimmed which rises to the surface. In 1916, 1200 tons of glycerin was saved by the British armies, which translated into shells equals one million and a quarter 18-pound shells.

I was going through a Portuguese camp in England with a splendid type of British colonel who accompanied us. He noticed under a Y. M. C. A. hut an insignificant pile of note-paper. I thought the old fellow would have a stroke of apoplexy. He called out all the men who

were supposed to be responsible and he gave them the worst tongue-lashing I ever heard. After visiting several other camps that afternoon, he finally turned to me—evidently it had rankled in his mind all day—and said, “Major Penrose, I’m awfully sorry that you saw that pile of note-paper under that Y. M. C. A. hut, but remember it was a Portuguese and not a British camp.” This thought gave him some consolation.

I also went through some of the sanitary schools and the Royal Hygienic Institute, where food captured on German prisoners is analyzed. The German soldier is not faring any too well, judging from the rations I saw examined; the odor and appearance were not appetizing.

England has out-Germanized the Germans in scientific investigation, under the incentive of this war. She has encouraged her foremost scientific men to make the most painstaking investigations. Certain discoveries have been made that would almost justify this terrible war but for its horrors. I will here instance two or three of them in order to illustrate this statement.

Since it has been necessary in modern warfare for a man to expose himself, especially the lower extremities, to cold and wet, it has been rather interesting to note that a rather serious condition of the foot has developed, which is called “trench foot.” There are three stages of this condition—the simple edematous stage where the foot is cold and swollen, bluish-looking, congested, and tender on manipulation, with a sluggish circulation. Second, there is a blister stage; small blisters appear, often showing purulent fluid and often a hemorrhagic fluid. The third is the gangrenous or necrotic stage. Here we get gangrenous sloughs down to the bone and deeper tissues which frequently necessitate amputation. Then we find a fourth stage, a general riddling of the soft parts, with destruction of the bone. With the last there may be complications which will result in death, although this is rare. Several doctors in the French and English armies have made studies of this disease, and have found that it is not caused

by frostbite or chilblains, as it occurs in temperatures that are too warm for such conditions, the temperature being above freezing, and in periods of the greatest humidity. They have found by making investigations of the tissues involved that it is due to the inoculation into the tissues of several kinds of fungus growths. The three principal ones found are: First, *Scopulariopsis Koningii Ondermans*. The second is *Sterigmatocystis versicolor*. The third is *Penicillium glaucum*. These are three of the most prevalent fungus growths. The microscopical pictures observed in these lesions are quite characteristic, and similar lesions can be produced by inoculation from human beings into animal tissues. In the cases with *penicillium glaucum* it is necessary to previously expose the animal’s foot to prolonged immersion in cold water before it will take up the inoculation.

Many remedies have been tried, alkalis and camphor giving the best results. A borated camphor soap, consisting of camphor 25 parts, borax 10 parts, and green soap 1000 parts, is quite commonly used.

They train the non-commissioned officers to take care of the men’s feet and to give instructions in this care of the feet. The men put on dry stockings when leaving the trenches, and frequently the feet are rubbed with camphorated oil. Efforts are now made to keep the trenches as dry as possible, and the men are given rubber trench boots—high hip-boots. In the blister stage and in the gangrenous stage they use a camphorated ether—camphor 30 parts, ether 1000 parts. In the septicemic forms they use an injection of from 5 to 15 cc. of camphorated oil, intra-muscularly. Trench foot is similar in many ways to the Madura foot of the Indo-Chinese peninsula, affecting men who work in the rice paddies.

“Trench mouth,” or, as it is called, epidemic membranous stomatitis and gingivitis, is an old disease, Vincent’s angina, under a new form. It has occurred among men in the trenches in France, and especially those who have taken poor care of their teeth. The be-

lief is that eating hard food has also contributed somewhat to its development. Major F. B. Bowman of the Canadian forces has described this disease accurately and has outlined a very efficient treatment. The clinical symptoms are foul breath, bad taste, enlarged sublingual and submaxillary glands, swollen, spongy, and retracted gums with the characteristic membranous exudate, especially at the margins of the teeth. On rubbing this a bleeding surface is exposed, and the teeth when tapped with a little instrument are tender; so much so that mastication is seriously interfered with. The temperature ranges between normal and 102° F. The disease is especially marked at the junction of the teeth with the gums, and especially about the posterior molars, with numerous lateral spreading superficial ulcerations. These are noted over the sides of the cheeks; over the tonsils there is a tendency to burrow deeply.

The disease is communicable, occurring in groups of men using the same utensils or attended by the same dentist. Under the microscope a little of the exudate when rubbed up with a salt solution will show the presence of spirochetes in large bundles, and also a characteristic fusiform bacillus, both forms being motile and very slender, delicate organisms with five to twelve convolutions. The identity of this condition with Vincent's disease is therefore proved. One of the chief symptoms is great mental depression with malnutrition due to the men's being unable to eat. The prevention is to correct the dental trouble and make them, first of all, attend to the hygiene of their teeth and mouths.

The treatment that is most efficacious is arsenic. The following is a formula that Bowman uses: Wine of ipecac one-half ounce, glycerin one dram, with Fowler's solution one ounce. This is to be mixed and used as a mouthwash and applied with an applicator directly to the affected gums. A saturated solution of tartar emetic can be used in the above formula in the place of Fowler's solution. Recently they have found that the wine of ipecac is unnecessary, and the Fowler's solution or tartar emetic can

be used alone. Good results are obtained in the use of this treatment, even in severe cases.

Within a week most patients are practically well and able to masticate solid food. Formerly it took from three to four weeks to put men in shape to go into service. In the Royal Hygienic Hospital they have discovered a cure for beri-beri—simply the use of brewer's yeast, and a cure for scurvy by the use of sprouting beans. A man can take a certain quantity of beans and soak them twelve hours in water and then let them germinate for forty-eight hours between two sheets or blankets. As soon as the bean has sprouted it produces in itself a remedy both for the cure and prevention of scurvy. The chances are that pellagra and rickets and other diseases of a similar nature due to certain deficits in food can all be treated somewhat along similar lines.

The elements in the food which prevent these diseases are called vitamins. In scurvy it is an interesting thing to note that it is cured by fresh meat and vegetables, but the fresh meat must possess certain vegetable elements, *i.e.* it must come from vegetable-eating animals.

I cannot close an address of this kind without reference to the good work of the Y. M. C. A. and other similar societies. These bring into this war some very essential things, more important today than ever before. The average young man who enters the army now differs very materially from the old-time regular soldier. I know, having been reared as a boy in the old army; my father was a regular army officer. The soldier today is high-strung, like a race-horse; often better educated than his officers, he has been accustomed to diversion and home refinements which are greatly missed in the monotony of camp and field life. The Y. M. C. A., etc., with their simple little amusements and recreations, their refined men and women, bring into the life of the young soldier many things which he sadly misses. A poor young Western boy suffering from homesickness crept into a Y. M. C. A. hut in France. He sidled

along the wall and sat down, by himself, in the back part of the building. An attractive young Y. M. C. A. worker approached him and said, “Is there anything I can do for you?” to which he replied, “Gosh, lady, just sit down and let me look at you.” We have all felt like that boy, at times, in France, and can sympathize with his feelings. In this war for the reasons cited above, cordial relations between officers and men are most necessary, the old-time martinet as well as the officious yet inefficient young officer, will gradually drop out. As an English colonel tersely put it, “By Jove, you had better get along with your men, or they will get you from behind going over the top.” Even if this did not occur there are times when the men by a little extra effort could save their officer’s life, and if he is unpopular this effort is not made.

I treated an American soldier who came from St. James, Mo. His left eye was blown out and his left elbow was crushed by a shell. I remembered that I had treated the people after whom this city was named. The boy brightened up and he was made very happy when I mentioned some old familiar names. It is a great comfort to these boys to hear something about their home people. The case to which I have referred was especially pathetic.

Our American boys stood their wounds just as well as any other soldiers that I had seen in France.

Possibly because I was raised in the army as a boy, my interest in military matters was stimulated. I had written articles on such subjects and also delivered an address before the Baltimore Medical Association five months before England and Germany went to war. This address was practically a prediction of this war. The *New York Times* after the war was declared published this article in full (October 4, 1914), and also the *Army and Navy Journal* wrote an editorial on it. In this article I emphasized certain conditions.

Although we were spending, I stated, more money on philanthropy than any other country in the world, we were unfortunately showing a greater percent-

age of murders, suicides, and imbeciles in our population. Thirty per cent. of our defectives were of foreign birth. There were too many people in our midst who were adopting a number of erroneous philosophies and cults in the spirit of self-justification. Some mothers, tired of sitting up with sick children, adopted a mental cult which enabled them to sleep at night and let the babies yell. The anarchist, born with the lack of desire to work, became a morose and unhappy individual until anarchy was given him as a panacea. The pacifist, not liking to fight, took up pacifism. He would fight hard enough if one tackled his pocket-book or usurped any personal prerogative.

We were gradually establishing a number of peculiar cults and rattlebrained philosophies. Germany, on the other hand, was formulating but one fell philosophy, that “*Might makes right*,” together with a gradually growing efficiency. What could be the outcome? War was inevitable sooner or later.

We have sent our youth to this war, and the youth of a country is the best part of any country, because the ideas of youth are living and potential, while as we get older our ideas are more or less dead and dying; we are hampered by our traditions, by experience, and we count the cost. Our boys over there do not count the cost. What would you think of a soldier who did count the cost? He would not be a soldier at all.

It was absolutely necessary for every man, woman, and child in this country to get back of the fighting men in the same spirit that England has gotten back of her fighting men and not count the cost either. The thing that worried me at first was the uncomfortable feeling that perhaps we might fall short in this.

When we come to realize that the atrocities are absolutely true, that these barbarians are indulging in an inhuman warfare and our boys will suffer at their hands, we will fully awaken. The British soldier will never forget certain events which have happened, and every soldier in the Allied armies is surely developing many bitter memories.

Conduction Anesthesia.

By J. N. C. MOFFAT, D.D.S., Shelby, Miss.

(Read before the Mississippi Dental Association, Meridian, April 16-17, 1918.)

LOCAL anesthesia in its various forms successfully employed is the greatest practice-builder at our command, as it enables a dentist to do thorough work with a minimum amount of pain. The public knows that this is being done by ethical practitioners, and is beginning to demand it more and more.

The remark is often made that nerve-blocking is difficult and complicated. It is, if a man thinks he can employ the same careless technique that is usually employed when an injection is made into the periodontal membrane for a simple extraction. It is not, if the proper technique is carried out.

If we know the nerve supply to the different teeth and surrounding tissues, and are familiar with the anatomical guides that will enable us to inject a sterile solution around these nerve trunks, then all we need is practice. Of course, I do not mean that a man can start into this work and get gratifying results without some preparation, but I do mean that any dentist of ability along other lines, who will apply himself and will observe carefully the smallest details of asepsis, can and will get gratifying results.

It is my desire to make this paper absolutely practical, and for that reason I shall not discuss the various technical methods of producing anesthesia, nor any phase of the subject except those which are concerned in our everyday use of local anesthesia. This paper therefore is intended for four classes of men:

First: Those who use nerve-blocking frequently with success.

Second: Those who have used nerve-blocking frequently without success.

Third: Those who have learned something about the technique but for some reason have not tried it.

Fourth: Those who are not familiar with the technique.

The first practical discussion of nerve-blocking I ever heard was at our meeting in Jackson, by Dr. S. L. Silverman of Atlanta. He made it appear so easy and practical that I was extremely interested, and asked him this question at the close of the lecture: "Is there a textbook on the market that will enable a man that is unfamiliar with this work to get sufficient practical information to enable him to do nerve-blocking successfully?" He said "Yes," and recommended Fischer's book. I bought one of Fischer's books, read just enough to know that I did not know anything, and laid it aside. I did not attempt nerve-blocking until two years later. I have since learned that if a man will get Fischer's book on local anesthesia and study it carefully, and will get just a little practical demonstration from someone, he can do nerve-blocking.

INSTRUMENTARIUM.

Now let us take up the practical aspect. The first thing to do is to get a suitable equipment. It is not necessary to buy everything the experts say, but if you are going to economize on the essential parts of the equipment you had better let conduction anesthesia alone. The next thing needed is a place to keep that

equipment. If it is stored away in a cabinet drawer it will be necessary to boil everything each time you use it. Purchase a sterilizing jar made for the purpose and fill it with 70 per cent. alcohol. The other essential parts of the equipment consist of a suitable hypodermic syringe without washers that will hold at least 3 cc. of solution; a short needle 15 mm. in length; a straight needle 30 mm. in length; a 30 mm. needle with curved shank for tuberosity injections; a 3 cc. novocain dissolver, and a 10 cc. dissolver. It is best to use iridio-platinum needles, because they will not corrode and can be heated to a cherry red as often as desired.

It is also desirable to have a study skull. I do not believe a man can make a success of nerve-blocking unless he has a skull to use in his study when he begins. I suspect there are men present who have made failures in their injections who would have been successful if they had had a skull to freshen the memory in regard to the anatomy of the region before making those injections.

The E tablet will meet all requirements, so we will not discuss the different tablets, which vary in suprarenin content. Only distilled water and Ringer's tablets should be used for making the solution to which the E tablet is to be added. I use a Silverman still and distil my water fresh every day and usually immediately before making solutions.

PREPARATION OF THE SOLUTION.

Let us now describe the preparation of the solution. I first remove the 10 cc. dissolver from the sterilizing jar, fill with freshly distilled water, boil thoroughly, and then empty it. This is done to remove all traces of alcohol, and, as an additional safeguard against infection, before placing the distilled water with which I am to make the Ringer solution in the dissolver. We then place a little more than 10 cc. of distilled water in the dissolver, and boil. If freshly distilled water is used, it is not necessary to boil for any length of time. One

Ringer tablet is placed in the 10 cc. of distilled water, which gives a physiologic salt solution. We then pour 3 cc. of this solution in the 3 cc. dissolver, which has been previously prepared for it by boiling distilled water in it, just as with the 10 cc. dissolver, before making the Ringer solution. We now add 3 E tablets, or 1 E tablet to each cc. of solution, which gives a 2 per cent. solution, the strength usually employed in making the injection.

Select the needle indicated, adapt it to the syringe, and wash the syringe out several times to clean it of alcohol by drawing in and expelling sterile distilled water several times. The needle is then heated to a cherry red and the syringe filled with anesthetic solution ready for the injection. We now have a 2 per cent. sterile solution that is isotonic.

METHOD OF MAKING INJECTION.

We are now ready to prepare the field for the injection. We must always remember that we are going to inject this solution into the deep tissues. Spray the mouth thoroughly with some antiseptic used in routine work; dry the point well where the needle is to be inserted, and wipe the tissue with tincture of iodine. The needle should always be heated to a cherry red before making the injection and before drawing the solution into the syringe. The solution should be as near the temperature of the body as is practicable. I test it by dropping a few drops on my forearm. If I cannot feel the temperature of the solution, it is a fairly safe guide that the temperature is approximately correct.

I may say just here that there are two points that will prove of invaluable assistance if one will carry them out in every instance. These two points were deeply impressed upon me by Dr. Silverman: If in making an ordinary injection the patient should show any unfavorable symptoms, the first step would be to place him in a reclining position: so why not do this before making the initial puncture? The other point is, to

avoid making the injection too rapidly. Dr. Silverman says that sixty seconds by the watch should be the minimum time required for making the injection. When I make an injection, my assistant stands behind the chair with a watch in hand, and my minimum time is nearer two minutes than sixty seconds in most cases. You should be careful to distribute the solution equally for the entire time. If you consume sixty seconds in injecting one-half of the solution and then inject the other half at once, you have destroyed the effect of the slow injection.

There is another important point. When a patient presents himself for an operation with a well-defined area of infection, we should not attempt a nerve-blocking injection if it is necessary to pass the needle through the infected area to reach the point necessary for anesthesia. Do one of three things: Hurt the patient as much as is necessary, administer a general anesthetic, or do not attempt to operate.

I shall now hurriedly describe the fields covered by the various injections. In the upper jaw the tuberosity injection will produce anesthesia of the second and third molars, and in some instances the first molar. We cannot rely upon anesthesia of the first molar in a tuberosity injection, on account of the distribution of the middle superior dental branches. Infiltration anesthesia should be em-

ployed for the two bicuspids and the first molar when necessary.

If a nerve-blocking injection instead of infiltration is made for the six anterior teeth, it should be made at the infraorbital foramen, but remembering that the success of this injection depends upon the solution getting back into the infraorbital canal. If infraorbital injection is used for only one side, infiltration must be employed at the median line if an operation is to be performed on a central incisor, to block off sensation from the nerves anastomosing from the other side. If the lingual surface is involved in an operation on the upper jaw, a lingual injection is necessary to block off the naso-palatine or anterior palatine branches. In the lower jaw, infiltration may be employed for the six anterior teeth, but the mandibular and mental injection should be used for the posterior teeth. The lingual nerve is blocked in making the mandibular injection, which produces anesthesia practically to the median line, where it meets the injection from the opposite side. If anterior teeth only are to be removed, the lingual nerve may be blocked at any point along the lingual surface.

I realize that one cannot do nerve-blocking successfully simply from listening to what I have said, but I believe I have suggested some points which may be of some assistance to each of the four classes for which this paper was intended.

CORRESPONDENCE

"Sulfuric Acid in Root-canals."

TO THE EDITOR OF THE DENTAL COSMOS:

Sir,—As Dr. S. J. Kessler has brought forward the question of the respective self-limiting action of sulfuric acid and of the sodium and potassium alloy in your October issue, I avail myself of the privilege of replying to his communication through the same channel.

In this instance, as is often unfortunately the case, a sentence lifted from a paragraph loses the identity, and in particular the significance, it possessed in the original text. In my article in the June issue of the DENTAL COSMOS I spoke of the fact that we should use only sodium and potassium as we approach the apical end of the canal, and that we should use it only in almost microscopic amounts. Then the sentence immediately preceding the one quoted by Dr. Kessler reads, "On this account we may safely go *through* the apical opening." This would of course indicate that I was speaking of the relative action of the two agents upon the immediately surrounding periapical tissues, and these are *soft tissues*.

The point at issue is then further clouded by creating the impression that I am at variance with Dr. Callahan, by quoting from him to the effect that sulfuric acid is self-limiting in cancellous tissue, and that sodium and potassium is not. Here lies the *apparent* difference. Dr. Callahan spoke of cancellous tissue, by which he meant hard tissue, and I spoke of periapical tissue, by which I meant soft tissue.

Anyone with a knowledge of chemistry would know that the action of H_2SO_4 would be limited in action in bony tissue, because the acid radical would be quickly

satisfied by combining with the high calcium content of cancellous structure. In fact, in looking over Dr. Callahan's original paper (*Items of Interest*, August 1915) I find that Dr. Prinz in his discussion went into detail on that point. There is a percentage of cases where the canal contents have completely dried out in which the application of Na-K, without the proper previous application of water, will result in a very gradual saponification of these contents and of the canal walls. In these cases the action is not, strictly speaking, so limited, and this was probably the case with the specimen Dr. Callahan presented. But with the proper technique this is not the case. However, in dentin the inorganic content is about 75 per cent. of the mass, and I spoke then only of its limited action on all organic matter. The action of Na-K is, as has been repeatedly pointed out by Dr. M. L. Rhein, largely due to its affinity for water, and all soft tissue has a high water content. This is the reason why we can so readily open canals and with the roentgenogram find in so many cases that accessory canals, often even at right angles to the main canal, have been cleaned of their contents and we are thus enabled to properly fill them. Na-K, in the extremely small amounts in which we should use it, when it touches any soft tissue instantly enters into chemical combination with it, and both lose their original identity, leaving in this case only such a trace of sodium and potassium hydroxid that its action is negligible.

Sulfuric acid, on the other hand, acts on soft tissue as a caustic or by virtue of its ability to coagulate albumin.

Its action on such tissue will continue uninterruptedly until its acid radical is entirely satisfied, and in soft tissue the inorganic salts are so small a percentage of the mass that they have no appreciable effect in limiting the caustic action. Therefore the action of sulfuric acid cannot be viewed as a self-limiting one in soft tissues.

We must consider not only the chemical reactions of these two agents, but also their physical characteristics. Na-K is an alloy of plastic consistence, so that we may pick up any amount at will and place it in the canal with the assurance that it will not pass through an opened apical foramen. Sulfuric acid is a liquid, and we can only apply it by placing a drop in the canal, and if the apical foramen be opened it can be and often is drawn through, coming in contact with the periapical soft tissues. Therefore if one feels that he must still use an agent so dangerous to soft tissues, when working in the apical third of root-canals, he should assuredly resort to the use of the paste form in which sulfuric acid has been recently introduced.

In order to test these reactions on living tissues, a guinea-pig was used. Making an incision through the skin, it was dissected back a short distance, exposing

healthy muscular tissue. On the one thigh so prepared was placed some sodium and potassium, much more than would ever be protruded accidentally through an apical foramen, and on the other so prepared was placed one drop of 50 per cent. sulfuric acid. The Na-K reaction was entirely confined to the point of application, while on the acid side the reaction was spread over quite an area, and was much more violent in appearance. This rather empirical experiment goes to prove the above explanation as to the respective actions of the two agents. These experiments, to be conclusive, should of course be carried out by working the agents through the root-canals of dogs' teeth, sections being made of the tissues, but I have not at present the necessary time to carry out such a long series of experiments, and I write this in order to demonstrate more clearly to any other investigator who may be interested enough to carry the work farther, this difference between hard and soft tissue when acted upon by these agents.

In conclusion I wish to thank Dr. Kessler for his interest in the matter.

Very cordially yours,

MILTON J. WAAS.

CAMDEN, N. J., November 11, 1918.

"Self-limiting Action of Sulfuric Acid."

TO THE EDITOR OF THE DENTAL COSMOS:

Sir,—Concerning the action of sulfuric acid on teeth, the late Dr. Geo. Watt, many years ago professor of chemistry in the Ohio Medical College, and in the Ohio College of Dental Surgery, this city, affirmed before a class that this acid was self-limiting.

Dr. Callahan, who is referred to in Dr. Samuel J. Kessler's contribution to the Correspondence column in the DENTAL COSMOS for October, once asked the writer if he knew whether or not this

acid was self-limiting. I referred him to Watt's "Chemical Essays," saying I thought Dr. Watt therein affirmed what he had stated before our class.

Dr. Watt spent many years elucidating his theory of acid decay of the teeth, affirming that sulfuric acid caused the black variety of decay, accounting for the slow progress of this (alleged) form of caries on the hypothesis that a minute portion of the nascent acid attacked a tooth, the action ceasing almost instantly. Again, conditions favoring its

production, another similar action would follow. Emphasis is to be laid, of course, on the affirmation (as to the acid being self-limiting).

Although candor requires that a former editor of the *Cosmos* once declared that Dr. Watt saw some things

in the microscope which "wer'n't there," the credibility of his express testimony on this point need not be thereby invalidated.

Respectfully yours,

FRANK W. SAGE, D.D.S.

CINCINNATI, O., October 11, 1918.

"Professional Capability and Dental Commissions."

TO THE EDITOR OF THE DENTAL COSMOS:

Sir,—In your October issue, Dr. R. A. Clark has written a letter entitled "Professional Capability and Dental Commissions." I think some things that he has written should be cleared up. For instance, he has said that he has in mind at the present time three young men, experienced not only in every branch of dentistry but also in anesthesia, surgery, and medicine, who are or will be drafted as plain privates, while inexperienced, newly graduated men are wearing the officer's uniform. I suppose that it is unjust (?) that the above three men did not have the patriotic spirit to volunteer for commissions, when commissions were to be had, instead of waiting to be drafted.

Dr. Clark also does not know that these "inexperienced, inefficient 1918

graduates" can put many of the older practitioners to shame, on account of their receiving special courses in war surgery and fracture work. The main idea in Dr. Clark's mind is that recently graduated men are not so good as those who have been in practice for years; but experience is not the main thing.

However, the whole question of commissions is remedied now, in that the United States Government has increased the *personnel* of the Dental Surgeons Corps, and Dr. Clark, his three friends, and older experienced men, as well as the "inefficient" 1918 graduates can (if ability counts for anything) get commissions.

Very truly yours,

BENJ. DANIELS, D.M.D.

DORCHESTER, MASS.

PROCEEDINGS OF SOCIETIES

Maryland State Dental Association.

Annual Meeting, held at Baltimore, Md., June 6-7, 1918.

THE annual meeting of the Maryland State Dental Association was held in Odd Fellows' Temple, Baltimore, Md., June 5, 6, and 7, 1918.

WEDNESDAY—*Evening Session.*

Dr. Eldridge Baskin, Baltimore, president, called the convention to order at 8 P.M. Wednesday, June 5th.

Rev. J. M. GILLUM of Baltimore opened the meeting with prayer.

As the first item on the program of the evening session Dr. Baskin introduced to the audience Major CLEMENT A. PENROSE, Baltimore, of the medical corps of the U. S. army, who gave an address entitled "Some Experiences in the Camps and Fields of the Armies Overseas."

[This address is printed in full at page 1119 of the present issue of the DENTAL COSMOS.]

DISCUSSION.

Dr. B. Merrill Hopkinson, Baltimore. I want to ask Major Penrose in connection with "trench mouth," if the treatment was entirely local, and was confined to Fowler's solution?

Major Penrose. The dental treatment was practically local, and it is surprising how these cases cleared up. There were splendid results secured in a few weeks' time: formerly it took anywhere from four to seven weeks. The

effect of Fowler's solution in those cases is remarkable.

Dr. H. E. Kelsey, Baltimore. Did I understand Major Penrose to say that they could not mill wheat on the other side, or that they could mill only wheat?

Major Penrose. They cannot mill any of the other cereals on the other side. The rollers are made only for wheat.

The society then adjourned until Thursday morning.

THURSDAY—*Morning Session.*

President Baskin called the convention to order at ten o'clock.

The PRESIDENT. Gentlemen, I am very glad to present to you Dr. NORMAN S. ESSIG of Philadelphia, who will now deliver a paper on "The Needs of Prosthetic Dentistry."

[This paper is printed in full at page 1108 of the present issue of the DENTAL COSMOS.]

DISCUSSION.

Dr. H. E. Kelsey, Baltimore. There are some ideas in the paper that are new to me, and I would like to say that I hope Dr. Essig's investigations will be studied with a great deal of interest by the orthodontists, as he has most clearly presented his ideas. There is much in the paper that will be of the greatest value to those who are dealing with nat-

ural teeth as well as those who are dealing with artificial teeth.

Dr. B. Holly Smith, Baltimore. I think Dr. Essig is wrong in his terminology. He applies the word robust to the cuspid tooth. I think he ought to use another term. He might say the militaristic cuspid tooth. I would be satisfied to describe the cuspid in that way.

I was much interested in Dr. Essig's essay. In the classification of teeth it has always seemed to me that the third molar is the only one where we must make apologies for its lack of space. The lateral incisor is designed by nature to give a softened or feminine expression to the face, and may be forced by other more essential teeth into an inferior position for its development. It seems to me that in the case of the third molar, as a result of the usurpation of the molar and its position down in the angle of the jaw, we might apologize for its distortions by lack of space; but does the lack of space influence the shape of those other teeth?

Dr. Essig. I rather think it does. There is a time in the developmental stage of any tooth when it is more or less pliable. I was not making an excuse for the lateral; I was simply commenting on it. I am perfectly willing to let it remain in its original condition without any faultfinding in the least, but it seems to me in the developmental stage it cannot be done. You cannot raise a husky or warlike lateral. In other words you cannot make a major-general lateral out of one that is only a corporal in size. It seems to me that any tooth under normal conditions takes the space allotted to it. The third molar has often more time. I think it is just a tooth with a bad disposition. It is not that it has no room to come through, but it just takes a notion to turn upside down; but the lateral tooth is not, to my mind, as unruly a member as the "wisdom" tooth. We see it in small children with the permanent teeth in their developmental process before the roots have thoroughly formed. We find the whole capsule is so soft that it could very readily be distorted. I think if there

were more room for the lateral there, it would not be so long and narrow; it becomes a long, narrow tooth. If the space is sufficient the teeth are not deformed. You often see queer teeth with ample space between them and other teeth of the same size. I am speaking of the form in the firm, well-developed mouth where there is ample room. I do not say that that always takes place, but especially in teeth of large size going into small arches without being unduly crowded. It seems one way in which nature takes care of affairs, and it becomes ideal. In the models I showed on the screen, with the dissimilar laterals, especially those of the hooked shape or banana shape, those mouths were all comparatively regular, with very large teeth in small arches.

Dr. B. Holly Smith. I fear that I had the appearance of a little rudeness in my reference to the term "robust." I appreciate very highly Dr. Essig's paper. I think he has accomplished something that he may well be congratulated upon. In this day and generation things modern have sometimes swept us away, and every man of us here likes to at least try to put his faith on a right and a sure foundation. Dr. Essig's heredity places him on a firm foundation. He was born and bred and raised right along that line; he has lived that life, and the life of what we used to call a mechanical dentist.

What do you commend, doctor, as the best base for plates? It seems to me that for the great majority of purposes it should be vulcanite, or a combination of gold and vulcanized rubber. I believe some of the most satisfactory plates or dentures I ever made as far as adhesion is concerned have been rubber; yet I can call to mind other plates which also were satisfactory in their adhesion.

Dr. Essig. I think in the majority of cases rubber is most satisfactory. One case I have just made was one in which the patient had had six dentures made in rapid succession, and could not retain any one of them in the mouth or use them in the slightest degree. I do not know the man who made the dentures,

but the dentist had finally given up, saying, "I cannot do it; you have a queer mouth: I do not know what to do." I was a little nervous, as I thought that I had come across one of those "hoodoo" mouths, where for some unaccountable reason there was some insuperable difficulty, but it was one of those cases where you feel that you want to do your best, and I undertook it. I took the impression with the Hall method. When finished the patient could not get the plate out without the use of a glass of water. I could not get it out, and he said he had to fill his mouth with water and drive the water under the plate to dislodge it. There is always much to say in favor of the gold plate, but in many instances a patient cannot afford one. I do not believe that so far we have anything that has superseded either gold or rubber as a base for artificial dentures.

The **PRESIDENT**. Next on the program is an essay by Dr. A. H. PATERSON of Baltimore, entitled "Careful Technique the Greatest Factor in the Construction of Full Upper and Lower Dentures."

[This paper was printed in full at page 876 of the October issue of the **DENTAL COSMOS**.]

The meeting then adjourned until the evening session.

THURSDAY—*Evening Session.*

The President called the meeting to order at eight o'clock.

The **PRESIDENT**. We have with us this evening Dr. L. ASHLEY FAUGHT of Philadelphia, who will read a paper on "The Conservation of Approximal Interspaces, Together with the Adjustment of Occlusal Relationships."

[This paper was printed in full at page 976 of the November issue of the **DENTAL COSMOS**.]

DISCUSSION.

Dr. B. Merrill Hopkinson, Baltimore. I want to ask a question. Do I

understand you to say, Dr. Faught, that all cavities should be cut down below the gum line?

Dr. Faught. That is the idea.

Dr. Hopkinson. I am sure everything that the doctor has said is good.

Dr. Arthur B. Crane, Washington. There is nothing that I can say except in commendation of what has been said by Dr. Faught. Everything the essayist has said agrees with my own opinion, and I wish to congratulate the audience on having had the opportunity to have these things pointed out, and placed before us so forcibly.

Dr. C. C. Harris, Baltimore. It is very gratifying to hear something along the line of operative dentistry, and I would like, if I had a good memory, to say a great deal on many of the points that have been touched upon. Looking after articulation or occlusion is certainly an important part of every dentist's work, and applies to every patient who is from thirty to forty years of age. Wear on the teeth forms inclined planes which force the teeth from their normal position, causing interdental spaces that are never kept clean, and results in all the ravages of decay and pyorrhea. A great deal of pyorrhea is brought about from teeth losing their normal occlusion, thus causing pressure irritation to the alveolus not intended by nature. It is certainly very important that the interdental spaces should be well cared for, with fillings so constructed as to prevent the forcing of food into the spaces. I certainly must take issue on the point of cutting all the approximal cavities down to the gum margin, when so many cavities can be saved with small fillings through many years—possibly ten to fifteen—and if we can gain that much with the small filling it is so much added to the life of that tooth. We may be forced to come to large fillings later, but let us delay them as long as possible. It seems to me that it is our duty to do this, it matters not how many fillings we must insert during a patient's lifetime. It is our duty to preserve every small quantity of structure, even though several fillings be required to preserve

a tooth for its longest usefulness. I do know that teeth are wonderfully preserved with non-cohesive gold, and far better than with any other material or method. I do not think our so-called up-to-date materials are in the non-cohesive gold class at all as to tooth preservation. It is superior, and does away with the extreme cutting that is so frequently found. These fillings can be inserted in such a manner that only the patient and the operator need know anything about them. I have some such in my mouth, and have had them for forty years, which do great credit to the operator.

Dr. W. W. Dunbracco, Baltimore. Mr. President, I want to thank Dr. Faught for his paper. I recall his first essay before our society; I remember him when I first came into this association, and have always identified him with the early years of this organization.

Speaking of non-cohesive gold as the filling material at the cervical border, the difficulty is in getting the right contact point. He says it should be below the gingival border. I want to ask him if he makes his fillings which go into the approximal surfaces entirely of non-cohesive gold, or if he does not use it for a certain distance up or down, and if he *does* use non-cohesive gold throughout, can he retain that contact point? That is the trouble that most of us seem to have—getting that contact point.

Dr. Faught (closing the discussion). Mr. President, I think I have but very little more to say, and do not wish to detain you any longer, but inasmuch as Dr. Dunbracco has asked a question, it seems to me proper that I should answer it. He refers very correctly to the difficulty of making the contact point when non-cohesive gold is used entirely. In practice I use it to a certain distance, and then finish in the usual way with the adhesive foils; it is only in that way that we can get the hard contour.

I was pleased with the remarks Dr. Harris made. He called attention to a thought which was in my mind. It is a fact that as we all grow older, and our tissues grow older, there is a certain

amount of wear which produces conditions where the tooth assumes an approximal relationship which is not normal, but which is decidedly abnormal, and which causes a great many of these difficulties we find in patients advanced in years. That is very true, and it is one of the things which demands from us the most watchful care in our treatment of these tissues.

There are one or two other gentlemen here, Dr. Hopkinson among others, who expressed the thought of extending the cavity below the cervical border. When I prepare a paper for a body of this kind, to be read upon an occasion like this, and it subsequently finds its way into the current literature, I am very careful, with these thoughts in mind, not to say anything extreme in my paper, simply because one does not care to open oneself to attack when possibly not present, and to which no answer can afterward be made. The criticism is very well taken. It reminds me, however, of a conversation which I had with several gentlemen in Philadelphia in which we were discussing this very question—the extension of the cavity for preservation of the tooth tissue. Not only in the matter of the cervical relationship, but more particularly with the thought in mind that we should bring the line of juncture between the filling material and the tooth tissue from a point where decay is liable to a point in the tooth where decay is less liable. This relationship approximately often brings that line of juncture into view; in other words, we mar the beauty of the tooth by so doing, even though it be good practice, and it is orthodox teaching. One Philadelphia practitioner said, "Gentlemen, that is all well, but we do not do it. And what is more, our patients do not want us to do it." There is a good deal of truth in what he said. The idea of extension is good sound practice, but we do not all do it, and many times when we feel called upon to do it, in the lateral relationship we decidedly do not do it, and the patients do not want us to do it. So you must read into the paper that which I did not wish to include, and the point

to which Dr. Harris has called attention. We may put in one, two, or three successive operations if need be, in order that the gum tissue may rest against the tooth tissue for so many years longer. Just as soon as we bring the filling material down in this relation it produces a pathological state; it is abnormal, and from that fact this filling material must produce more or less trouble.

I think I have clearly stated all these things now, and as I have nothing further to say except to thank you one and all for the very courteous reception and very courteous discussion of the paper, I will take no more of your time.

The PRESIDENT. We have with us tonight Dr. EMERSON R. SAUSSER of Philadelphia, who will read a paper on "Root Resection."

[This paper will be published in full in an early issue of the DENTAL COSMOS.]

The PRESIDENT. Dr. Homer C. Brown of Columbus is unable to be present with us this evening. He has just telegraphed us requesting that a resolution be sent to Congressman Talbot, Washington, expressing our appreciation and commendation to the Senate for passing the dental bill. What is the will of the body with regard to this telegram from Dr. Brown?

Dr. KELSEY. I think it would be well to pass such a resolution, and send it to Washington as Dr. Brown suggests, and I make that as a motion.

The motion was seconded by Dr. Hopkinson and unanimously carried.

The President, in accordance with the motion, ordered a resolution prepared, and the convention adjourned until Friday morning at ten o'clock.

FRIDAY—Morning Session.

President Baskin called the convention to order, and introduced Dr. J. V. CONZETT of Dubuque, Iowa, who delivered a lecture on "Operative Dentistry."

The PRESIDENT. Next in order is a paper by Dr. ARTHUR B. CRANE of

Washington, entitled "When Shall Root-canals be Filled, and How?"

[This paper is printed in full at page 1093 of the present issue of the DENTAL COSMOS.]

DISCUSSION.

Dr. Emerson R. Sausser, Philadelphia, Pa. I had the privilege last night of reading Dr. Crane's paper, and I enjoyed it and derived much benefit from it. He is always convincing, and his paper shows study and thought, with the result that he gives us something original and practical to help us forget our difficulties. With regard to the attitude of the physician toward the dentist, it is very natural that the medical man wants to be thoroughly convinced that the dentist has eliminated the condition of infection existing at the apical region of the tooth, which is causing his patient systemic infection, and in the absence of scientific proof that dentistry is eliminating these areas, he will very naturally take the matter into his own hands, and suggest extraction of the diseased organ.

The essayist has made a scientific effort toward proving the practical value of his medicinal treatments in cases of periapical infections, by making a bacteriological determination of the tissues before filling the roots. He has thoroughly checked up the conditions on his culture media, yet it is questionable whether he can determine conclusively the bacteriological contents of periapical origin via the root-canal.

The area of infection may lurk below the apex, down toward the body of the root, and not be reached by his method. No doubt it is in the essayist's mind to add to his technique by means of reaching this through the alveolar plate; at any rate, such scientific deduction as his method allows should be of great practical value during the course of treatment.

A clinical investigation such as Dr. Crane is making is just as important and essential to the investigations of the research laboratory as the latter is to the former; by checking up the findings of each, scientific progress is made. As to

future bridge work, the application of the pin inlay as an anchorage to conserve the dental pulp and the tooth structure should receive more universal attention.

Dr. J. V. Konzett, Dubuque, Ia. I wish to express my appreciation of Dr. Crane's paper. He has long since demonstrated the fact that he is one of the very best authorities in the United States on the subject of root-canal treatments. He has given another proof, by the splendid paper which he has read this morning, of his ability along those lines. There are several points in his article which are absolutely new to me, and I want to commend them highly, particularly that part which has reference to apical abscess, filling-in of the apex with gutta-percha by the simple method of pressing down on the tooth after filling the canal. That seems to me a very important point. There is just one other thought. Such papers as Dr. Crane has given us make it our duty to do the work Dr. Crane has done as he has presented it here. A great many dentists will say that they cannot do it, that they have not the ability; they become discouraged, and go back to extraction.

By a study of my radiographic results I find it is not necessary to fill all root-canals absolutely to the end of the canal to obtain satisfactory results. In our histological studies we learn that where the pulp passes through the end of the root the canal is lined with cementum, so there can be no odontoblasts in that portion of the pulp. If there were, we would have a lining of dentin in that portion of the canal. It is a well-known fact that in certain cases there is a sealing over of the end of the root by the cementum under certain conditions. If we force the root-canal filling to the end up through the canal we prevent the physiological condition of the sealing of the apex. If we had no infection, or prevented infection by any organism; if we use no irritant that would prevent the physiological functioning of cementoblasts, we get a sealing over of cement, and in many instances the root-canals will seal over and

give perfect results throughout the life of the individual. This thought has given me a great deal of comfort, and I believe that it will be of comfort to others. The prime object is that we must take aseptic precautions in filling a root-canal, and not allow any contamination of that root-canal whatever. If these precautions are observed in the filling of a root-canal it will not be necessary to go beyond and over the apex to get results. I do not mean to criticize Dr. Crane for a minute, for I might not be able to fill every root-canal as he does. But I do say that every man cannot do the work Dr. Crane does, and even though you cannot fill to the very end of the root-canal, if you fill it aseptically you may feel sure that you are taking good care of the people who come to you.

Dr. B. L. Taylor, Washington. Dr. Crane's paper omitted a matter of importance in regard to surgical rest when undergoing treatment. I think that is a point that is overlooked entirely by the dental profession. When a surgeon operates on a patient, if it is an important operation, that patient is given a rest after the operation takes place. We dentists treat teeth every day, leaving them to perform the same functions as when they were perfectly sound. I made a suggestion in a meeting some time ago that where the pulp has been removed the tooth should be ground off sufficiently to allow that tooth surgical rest from pressure during mastication.

With regard to Dr. Crane's paper, I want to say that we are all proud of him in Washington. We know that whatever he does is not done in a haphazard manner. I have seen many cases treated by him where he made all sorts of specimens to check up his work, and it is only those of us who have been associated with him that know the immense amount of time he has put on this subject. We know that what he does is scientifically correct, so far as scientists are able to carry out these theories at the present time.

Dr. Crane (closing the discussion). It is always a pleasure to read a paper in Baltimore, because it is received so

kindly. Dr. Sausser, I think, misunderstands me on bridge work. Very few of the abutments he mentioned are adaptable for removable bridge work. In the paper I said that devitalization would continue until some more efficient method is presented for removable bridge abutments. I think Dr. Tinker and Dr. LeGro are working along these lines, and am sure that before very long much devitalization is going to be eliminated by improvements in attachments for vital teeth. I personally deplore the necessity for devitalization; not that I feel that it cannot be done in a successful manner, in some cases, but there are so many chances for rendering a healthy tooth an unhealthy one. Dr. Conzett's caution about not filling quite to the end in cases of recent aseptic devitalization is a point very well taken. When I take out a normal pulp I would rather the filling would fall short than go through the end. The ideal method is to fill exactly *to the end*. In many cases where the pulp has been normal the terminations of the canal are filled with normal living tissue. Unless infection takes place and this tissue becomes gangrenous, it will remain vital and healthy for many years. When infection has persisted until periapical tissue is destroyed, then only should the filling go beyond the root-canal proper, but only far enough to cap the cementum exposed by the absorption of the pericementum. Filling a canal just to the end, while the most difficult of all root-filling, is not impossible of accomplishment. In the effort not to overfill the root, perhaps at first we underfill it, but a drop of chloroform placed in the chamber and worked in as described in the paper will in a large majority of cases make a perfect filling in those cases which otherwise might later on be seized upon by some fellow practitioner as evidence of our lack of skill.

Dr. Taylor's reference to surgical rest offers an important step forward should his theory be borne out. He suggested this method some time ago, but I have not had enough experience with it to know whether it is of any material as-

sistance or not. I think, however, it is well worth trying out.

In closing the discussion I want to give a brief answer to the two questions asked in the subject of my paper. One, "When shall root-canals be filled?" The answer is, Only after the sterilization of the tissues has been demonstrated to a reasonable certainty. Under present conditions we cannot have an absolute assurance of this fact, but we can be certain that when we get a growth from a tooth it has not been sterilized. Second, "How shall root-canals be filled?" In such a manner that all dead tissue is covered with filling material, whether such dead tissue is in the canal or at the end of the root.

The meeting then adjourned until the evening session.

FRIDAY—*Evening Session.*

President Baskin called the convention to order at eight o'clock.

The PRESIDENT. We have with us this evening Dr. JOHN OPPIE MCCALL of Buffalo, New York, who will deliver an essay on "Primary Factors in the Etiology of Periodontoclasia."

[This paper is printed in full at page 1084 of the present issue of the COSMOS.]

DISCUSSION.

Dr. H. E. Kelsey, Baltimore. I had the pleasure of reading a copy of the paper which was sent to me by the essayist, and I was particularly interested in it from his viewpoint of the term traumatic occlusion. I think, however, that in the essayist's remarks during the showing of the lantern slides, he made clear a point that was not so clear in his paper as he intended to make it—that was the difference in the extent of the injury which could occur in traumatic occlusion in adults and young patients. The point he brought out was that often in an aged person or adult an occlusion might become traumatic which would not in a youthful patient. I believe this is true; a condition which would be certain al-

most to produce a pathological condition in an adult would only act as a stimulus in a youthful patient. I think the period of the adaptability of the teeth to occlusal stimuli decreases after the twelfth year, when molars have been formed and erupted and all the deciduous teeth have been lost. From that time on, traumatic occlusion can become very serious, and I do not doubt, in fact I *know*, that in some cases even previous to that time, if it is sufficiently marked it can become a very dangerous condition.

The paper as a whole pleases me very much, and I think it is to be classed with several others by men all of whom seem to be willing to exert painstaking care in their observations. Dr. McCall's paper is more valuable than it might seem on the face of it. It shows the work and study that has been given to conditions that have been almost overlooked in the past, and also the difference between diagnosing from evidence obtained from every possible source, and snapshot opinions rapidly handed out on the sole evidence of X-rays. I think we are to be congratulated on having had this paper presented to us here. I wish personally to thank Dr. McCall for his presentation of this subject, especially that portion to which I have referred and which especially interests me, and I am sure will interest all orthodontists when they have had an opportunity to read the paper.

Dr. H. R. Coppage, Baltimore. I want to add that Dr. McCall's paper is not over our heads; we can appreciate the fact that the pressure of one tooth over another will give trouble, and if the pressure is traumatic it should be remedied. A case came to my office in which a crowned tooth was giving trouble because the crown was striking the opposing teeth too hard. I trimmed the crown down, and kept trimming it down until the teeth were occluding properly, and as a result the patient is today wearing that crown. It was very well constructed, and no doubt will continue to give good service. I thank Dr. McCall for the excellent paper he pre-

sented to us, and appreciate the opportunity and privilege of being present to listen to and enjoy it.

Dr. B. L. Taylor, Washington. I do not know when I have heard a paper that has pleased me more than this one of Dr. McCall's, for the reason that it is very concise and scientific, and what has gratified me most is that we have been able to adopt terms for the various diseases around the superstructures of the teeth. The etiology has been worked out very beautifully, and to my mind the essayist has not overlooked a single factor in the cause of the disease. The matter of the frequency of the disease is one of the points which I think is of interest to all of the profession. He mentioned the fact that the profession at large is not looking after gingival irritations. This is a fact, perhaps, which is noticeable more to those who specialize in prophylaxis, or treatment of pyorrhea, but it is a well-known fact that gingival irritations are allowed to exist in mouths where we find beautiful operative work being done. It seems the majority of dentists feel that they must make beautiful fillings, and that then they have done all that can be done for the patient. What is the use of a beautiful crown or a beautiful bridge or filling if the structures which support those teeth are going to become diseased, and the teeth gradually loosen and have to be extracted? It is the duty of the dental profession to do better work along this line. Cleaning teeth as it is being done in a great many instances should be abolished. I have had dozens of patients in my office say, "Why, doctor, I have never heard of anyone taking as long to clean teeth as you take. Usually they take from fifteen minutes to half an hour to clean my teeth." I tell them, "That is a fact, but I have to remove about fifteen years' deposits that should have been removed before." That occurs among the better class of operators today. The man who treats pyorrhea should never have anything to do except to work on advanced cases of pyorrhea, and there should be fewer of those. Dr. McCall has told us plainly that it seems

almost impossible to believe that any general practitioner should allow any case of pyorrhea to progress to a serious condition. I realize that probably seventy-five per cent. of our patients are patients who were cared for by someone else at some time, and we are not responsible for those conditions entirely, but if we are not capable of coping with the disease it is certainly our duty to send that patient to someone who can treat the case properly. There are too many dentists who feel that it is impossible to cure these cases. I have had a man in my own town say to me, "I do not like to treat pyorrhea." Is he doing those patients justice in not telling them of the lesions and the conditions about the teeth, and giving them the very best service? It is the duty of the dental profession to give better service. I realize that one reason why it has not been possible to do better work is the fact that the instruments manufactured heretofore for the removal of deposits around the teeth were very crude. There are very few of them that can be used successfully. In many cases it has been a waste of steel to manufacture such instruments, and the dentists are responsible in that they have never required or never insisted upon the proper instruments to use for the treatment of these diseases.

There is one point that I would like to bring out in regard to the treatment of pyorrhea. As Dr. McCall has said, we want a healthy flow of blood to the tissues, and we must secure that by massaging and frequent brushing of the gums. I invariably go a step farther, however, and insist upon the thorough mastication of food. I insist on a diet composed of coarse foods and vegetables; such foods as spinach, lettuce, celery, cabbage, and watercress, and coarse breads of all descriptions. I do not recommend this diet simply for the effect it has in mastication, in exercising the teeth and massaging the gingival margins, but also for the effect it has on the alimentary canal. In the ordinary diet, where there is very little fibrous food eaten, there is a tendency to the

formation of a pasty mass, which passes from the stomach into the alimentary canal and coats the intestines. There is something in the fibrous foods that stimulates the circulation as they pass into the intestines; they promote the flow of blood and produce a massage of the intestines. We thereby bring about a freer flow of blood, a better digestion, and a better assimilation of the foods, which eliminates any tendency to constipation. Chronic constipation can be cured by dieting and drinking plenty of water. This improvement in the systemic conditions when the local causes are removed will bring about a proper healing of those diseases.

Dr. McCall (closing the discussion). I appreciate very much the expressions that have been given here regarding my paper. It was my hope that I should be able to give you something practical. I had realized that in order to do that I would have to cover a good deal of ground. What I have stated has been said briefly; consequently I hope it will be possible for each one of you to read the paper if it gets into print, for in reading it you will get more out of it than by hearing it read. One of the things which actuates me in attempting to write papers or do any work outside of my office is my desire to assist, if I can, in enabling the profession to deal more capably with the diseases we are now speaking so much about. I wish to emphasize the fact that traumatic occlusion is excessive movement in the socket; in adults the movement is less marked than in children. When we have an excessive movement beyond the normal of the tooth in its socket, that is traumatic occlusion. I have presented five classes of periodontal diseases. I wished in a way that I could cut down that number, but I cannot do it. Black in his "Pathology" recognizes two classes of gingival and periodontal diseases. He mentions several others that do not fit in with either of those two classes. I do not believe we are going to gain anything by just considering two classes of disease, if there are five distinct types. I am very sure that I can point out each

one of those five types and frequently two or three types on one tooth, each of which has its own factors. Here is one very important point to remember—that every factor, primary and secondary, must be determined in diagnosing the case. If we discover two or three, but leave out the fourth, that fourth one will trip us up in treatment. There are two causes of our previous difficulties. One cause is a vague knowledge of the subject, not only by the general practitioner but by the man who thinks he knows something about it, and attempts to tell it. I am sure you have heard papers on the subject which were not at all clear, and I am attempting to clear this up for you by what I have given you. The other cause is lack of effort to master the technique of root surgery. When you have the instruments you must do some experimental work—work you are not going to be paid for—before you can expect to get results. I thank you once again for the very flattering reception you have given me.

The PRESIDENT. Next we will have a paper by a former resident of Baltimore, Dr. JAS. K. BURGESS of New York, who will read a paper on "Nature's Tolerance and Compensating Adjustments as They Relate to Oral Restoration."

[This paper was printed in full at page 986 of the November issue of the DENTAL COSMOS.]

DISCUSSION.

Dr. Geo. E. Hardy, Baltimore. Mr. President, each time I hear a paper from Dr. Burgess or hear him talk I wonder where he acquired that flow of beautiful language; he is never at a loss for the proper word to express his ideas, and his ideas are excellent. He is a practical man. I think the paper is a very desirable addition to our dental literature, and shall enjoy reading it over again when it is published. I repudiate his characterization of "assassin" for the practitioner who occasionally destroys a pulp to obtain proper anchorage. We have to construct, and there always arises

the question as to practicability. We must secure sufficient anchorage with the greatest possible conservation of the tissues to which we attach abutments. Occasionally the necessity arises for destruction or devitalization of the pulp. I have never attained to the degree of skill Dr. Burgess has in securing sufficient anchorage in all cases without encroaching too closely upon the pulp for the safety of that organ. We find it necessary too often to devitalize the tooth in order to secure sufficient anchorage.

Dr. J. O. McCall, Buffalo. I want to compliment the essayist on his paper. This is one, among the other papers I have had the pleasure of hearing, which I commend for the good common sense shown in the discussion of the subject. We talk about men being practical and having good common sense but not being scientific nevertheless. Science is always practical; it is always common sense. When you are scientific, so called, at the expense of common sense or of being practical, you are not scientific. At the beginning of the paper the essayist takes up the idea that we must spare the teeth remaining in the mouth as much as possible in the construction of bridges, and he rather hints at a system of bridge work which he mentioned in detail, but not by the name of the inventor—perhaps I had better not mention him by name either.

The great difficulty with bridge work in the past has been that we have not observed all the factors which caused the failure of bridges when we see the abutments becoming loose. When we say that the failure of a fixed bridge is going to be due to the fixation of the abutments and inability to move those abutments independently, then we are failing to observe the real cause of the failure of fixed bridges—which is the occlusion. It is not the fixation of the abutments that causes the damage; it is the occlusion. You can put a fixed bridge in a mouth, and if your occlusion is properly attended to and your bands are accurately fitted, then you are not going to lose that bridge.

Dr. H. E. Kelsey, Baltimore. I do

not feel qualified to discuss this question, but want to say in reference to the papers of both Dr. McCall and Dr. Burgess that it is always a great pleasure to listen to papers such as these, because they evidence the same careful and thoughtful consideration of details relating to every side of the subject. It is interesting to one who has been on the side lines (as the orthodontist is in relation to this particular subject) to notice the swinging back and forth of the weight of opinion concerning those subjects which are no longer under our direct observation, or at least phases of dentistry which we do not treat.

Many of the most successful men still insist on putting in fixed bridges, while others pin their faith to removable ones, believing that success or failure lies in the style of construction and attachment. It is significant that some at least recognize that neither form of bridge can be successful if a traumatic occlusion is established, and this has been well portrayed this evening. Indeed, I do not know when I have heard so many well-considered and interesting things presented as at this meeting, and I concur with Dr. Burgess' idea, if I get it correctly, that it is better in putting in bridges to have an occlusion which is not what is termed normal, but is the best adaptation of the restoration to the mutilated conditions, than it is to seek to establish in every instance a normal occlusal relation of the bridge to the opposing teeth, when the malposition of those teeth would require such a shifting of the bridge from the established occlusal stress as to produce what either is or will become a traumatic occlusion.

I wish to thank Dr. Burgess again for occasionally coming back to his home town, and giving us the benefit of his hard work and research along these lines.

Dr. Burgess (closing the discussion). Dr. Hardy takes exception in a mild way to my strictures on pulp devitalization, because, as he says, he has to destroy pulps himself. So do I, and so does every other dentist engaged in the work of restoration, whether of individual teeth or of impaired dentures. But I destroy

pulps—as Dr. Hardy does—under pathological necessity, or where the requirements of the organism demand restorations of such a nature that the engineering necessities of the case leave no alternative. My quarrel is with two classes of men: First, those who ruthlessly destroy a pulp without any consideration of its functions or the consequences which may follow. Second, the class of men to whom the niceties of mechanical execution—the love of tinkering, the external, the superficial—have an appeal that blinds them to the dangers to which their meddlesomeness exposes the whole systemic welfare. No dope fiend was ever more transported with his soothing potions than a removable bridge operator seems to be with the enslaving fascinations of his split pins and sliding crowns and other products of his mechanical art. If the tinkering were all done out of the mouth nobody would care, but it begins in the mechanical laboratory and ends in the root-canal, where that marvel of nature's handiwork, the dental pulp, must needs be sacrificed to make a tinker's holiday.

They talk of prophylaxis and sanitation as if these things had their beginning and ending in the oral cavity. It would be interesting and no doubt appalling as well to know how many infected hearts and kidneys and joints and other organs and tissues have paid the penalty of such men's lack of perspective and their silly insistence upon a microbeless mouth, let come what may to the rest of the organism!

Dr. Baskin wants to know my present attitude toward the shell crown, and I am very glad to answer his question. I have established as the four cardinal principles of all my own efforts at restoration surgery, engineering, art, and workmanship. These fundamental principles constitute what I call my "standard of perfection." I do not consider any method or measure, any system or technique, as an end in itself, but as a means to an end, and I check up the efficacy and the efficiency of every method and measure, of every system and technique, by this standard of perfection. I do

not vary my attitude toward the shell crown. Whenever I find it the choice of evils from these basic points of view I use it, and though the cases are rare they do occur. One very recent case presented such a condition. Briefly, it was a third molar, far short of the occlusion and so shaped and in such relation to the soft tissues as that it was scarcely necessary to touch any surface of it with a stone to shape it for a shell crown; whereas any interior method of attachment would have necessitated the usual amount of preparation. Now, the ends of good surgery demanded that that tooth be dealt with, other features being equally satisfactory, in the manner that required the least destruction of tissue. There was no question of the shell crown meeting all the engineering requirements. The tooth being far back and entirely out of view, the considerations of art were so minimized as to be merely sentimental. The workmanship in the case of the shell crown, as in everything else, is what we make it, though I have no hesitancy in saying that in all the realm of restoration there is no operation I know of that is so difficult, when one considers the entire operation from preparation to finished result, as the shell crown.

In some cases when a bridge with shell crown attachment is to be replaced it is found on its removal that the abutment teeth have been so ground away in the former preparation that one must choose between the shell crown on the one hand, and extirpation of the pulp for interior anchorage on the other. In such cases, where the considerations of art will at all admit of it, I choose the shell crown as the lesser evil. But taken all together and considering every class of case where I use the shell crown, it forms an insignificant feature of my restorative work.

I thank Dr. McCall for his part in the discussion, but especially for his own paper. To one who has worked in pyorrhea it is peculiarly interesting. My own paper proved in a measure to be a discussion of his, particularly of the part given to the consideration of

trauma. That part of the dental profession engaged in the work of restoration will learn the baleful influence of trauma, the relation of anchorage and occlusion, of stress and resistance, and of all these to trauma, and so to correlate and co-ordinate these forces as to procure the maximum of service without trauma inherent in any given foundation through the medium of a *rational occlusion*.

Dr. H. P. Cobey, Washington. I have been in silence from Wednesday until this time. The Essay Committee asked me some time ago to contribute something to this meeting. Conditions in Washington are unusual; the demands made on men in that city are rather unusual. As the time for this meeting approached I thought, for my own good, however, that it would be well for me to throw aside my duties temporarily, and spend the time here. I have attended this meeting from its beginning until this time, enjoying immensely the most excellent papers which have been given, and the fine clinics that have been shown. The thing which has struck me with the greatest force is the well-balanced program as arranged by the Essay Committee.

First, Dr. McCall's paper, dealing with one of the most troublesome conditions which the profession has to meet, was very interesting. He has very beautifully classified the conditions that come up under periodontoclasia, and suggested remedies for certain of those conditions; he also touched upon operative procedures.

We have had a fine presentation of the operating end of our profession by Dr. Conzett. If we have learned anything at all from Dr. Conzett's paper we have learned this—that by certain methods of operative procedure we can protect the septal gingivæ, which will prevent some of the troubles that were included under the head of Dr. McCall's paper.

We had an able paper by Dr. Crane. He told us or pointed out to us the classification of infections resulting from pulp exposures and troubles subsequent thereto. I think I can say that he has

presented one of the most scientific papers on that subject that has ever been given up to this time. He has not only classified these troubles, but he has in an orderly way undertaken to show how we might treat these conditions, and the class of cases we might find favorable for treatment.

Following Dr. Crane's paper we had presented to us by Dr. Sausser a splendid paper dealing with that class of cases requiring root resection for relief, the technique of which he very clearly described. We have also had Dr. Burgess' paper, in which he points out how nature will tolerate abnormal conditions, making it possible to substitute artificial devices. How well these papers are connected up! He tells us that where we have lost certain teeth and there are still others remaining, nature will permit us to use those remaining as abutments for bridges, supplying the vacancies. And I think he is absolutely right.

Next we have Dr. Patterson telling us

how to mount and articulate the teeth so that they may be worn and used with comfort.

I have never attended a meeting where I have seen such a well-arranged program, one that so completely covered the field, and I feel that I am very fortunate to be able to attend a gathering of this sort and enjoy it as a silent listener. I have profited immensely, and think that your association is to be congratulated on being able to have gotten together such a program; and the other men from Washington I know have enjoyed it.

The PRESIDENT. I want to express at this time our generous appreciation of the efforts of the essayists, and to assure you of our appreciation. I ask a rising vote of the society to the essayists. (The meeting rose in accordance with the president's request, and gave a rising vote of thanks.)

The meeting then adjourned.

Connecticut State Dental Association.

Fifty-fourth Annual Convention, held at New Haven, April 18-20, 1918.

(Continued from page 820.)

FRIDAY—*Afternoon Session.*

THE meeting was called to order at 2.45, Friday afternoon, April 19th, by the president, Dr. Bryant.

MR. SAMUEL G. SUPPLEE of New York City, gave a talk on "The Classification of Tissue Conditions in Partial and Edentulous Cases."

[This lecture was in substance the same as the paper read by the author before the New Jersey Dental Society, and published in the November issue of the DENTAL COSMOS at page 996.—ED.]

Dr. NORMAN S. ESSIG of Philadel-

phia, Pa., then gave an illustrated talk on "The Selection of Teeth in Articulation."

[This lecture was practically the same as that given before the Maryland State Dental Association, and published in the present issue of the DENTAL COSMOS at page 1108.—ED.]

The next item on the program was a lecture by Dr. EDWARD KENNEDY, New York City, on "Vulcanizing and Finishing Dentures."

[This lecture will be published in an early issue of the DENTAL COSMOS.—ED.]

The next item on the program was a paper by Dr. J. A. TURNBULL of Boston, Mass., entitled "Anaphylaxis in Connection with Asthma, Hay Fever, and Various Skin Diseases."

[This paper is printed in full at page 1112 of the present issue of the DENTAL COSMOS.]

Dr. GEORGE H. WRIGHT, Boston, in collaboration with Dr. Turnbull, prior to the discussion, gave a lecture on the same subject, as follows:

Mr. President, ladies and gentlemen,—Dr. Turnbull has given you a graphic illustration of how he determines the reaction to the proteins from various sources, whether wheat, or meat, or fish, or milk, or eggs. He tells you he washes the forearm with alcohol and takes a very weak solution of some of these articles of food, or clothing, or fur, or cat-skin, or dogskin, and makes a minute scratch, and in a very little while whatever that patient is particularly sensitive to, or reacts to, will show up better than anything else. He may have twenty different slight inoculations on the arm, and only one out of the total will give marked reaction, which appears usually in about ten minutes' time. This reaction shows as a circle about the size of a quarter, very red, and it comes on within ten or twelve minutes. After a quarter of an hour or half an hour it fades, showing that that individual is sensitive to that particular protein.

All mankind is made up of a complex chemical compound—no two of us essentially the same. I suppose that, in a sense, the difference is in our chemical makeup, which accounts for differences in mentalities as well, because we do react according to what we have within ourselves or what we represent in a sum total.

That is why in the olden days they had a saying, which you have often heard, "What is one man's meat is another man's poison"—and it is true. There are people here who know from their own experience that they cannot eat cheese, onions, eggs, oysters, or salmon without some marked disturbance. It is the ability to take care of

the proteins which are associated with these different articles of food which enables us to tolerate them, and not react uncomfortably to their presence. That is why one man can take three or four cups of coffee, or smoke six or seven cigars, and be perfectly comfortable; whereas another man would not be.

They have told us of this anaphylaxis—that from grasses, wheats, or meats we absorb certain of the proteins; and we may take them in in two particular ways: We may get absorption through the mucous surfaces of the body, through the respiratory tract, or we may be involved through what we have digested in the alimentary canal. That concerns us as dentists, because we are dealing with teeth which should prepare our foods through mastication for assimilation. We are told that proteins are made up of an acid and a base, and toxins, whether tolerated or not, are the result. When we speak of split proteins it means that the acid is separated from the base. Take away the base, and you have the acid.

I do not believe physiological or biological chemistry is all known today; much has to be learned. When we have diseased teeth we have about those teeth split proteins which are capable of becoming absorbed. When there is an acid near a bloodvessel or in the region of blood it prevents the coagulation of the blood. It renders the blood in that vessel or capillary so fluid and watery that it is taken up very readily in absorption.

We have, then, to consider the question: What becomes of the products of decomposition within and about the teeth, or the apical abscess, the first beginning of the alveolar abscess, or any degenerated product? Nature has given us walls of defense and means of defense, not only micro-organisms but other products, and chief among them is the highly vascularized tissue which is about the teeth. Dentists are learning more and more to respect those tissues. If a tooth becomes diseased from within the pulp, and you get the first expansion of the peridental membrane, and a breaking down of the bony tissue and a beginning of the granulomatous mass, you

have an evidence of what nature is doing in the way of trying to defend herself against what is being introduced there. You may know that the streptococcus viridans, when there is no oxygen present and the part cannot be bathed in sunlight, can be the most deadly organism that man has to deal with. Remote in its recesses, it produces many reactions. There must be a function for a cell; there must be something coming and something going, otherwise it ceases to function.

Round about the apex of the tooth, then, we have a walled-off membrane whose contents are capable of producing inflammation and irritating products. But those products do not stay there; they are given up, and as long as they are given up the micro-organism flourishes. How does that product become disposed of? There is a law throughout the entire body—the osmotic law—which governs the interchange of fluids. It is true within the interstitial tissues, it is true in the lungs and in all organs and glands, in bone, and in muscle. Wherever there is a fluid circulating and a fluid adjacent, even though there may be a membranous wall separating them, there will be an interchange. If you place a colored salt solution in a membrane, and place that membrane in some sterile clean water, in time you will see an interchange of the fluids. Under pressure, under the activity of muscular movement, under the normal functioning of the body, that process is active.

The whole body is bathed in lymph. If you take a section of the body you will find those lymph spaces bathed with fluid. That fluid is of less concentration than the products of bacterial activity, and the law of osmosis takes place wherever that fluid may be, even in the fluid contents of a cell. It does not always follow that that is a nutritive fluid, but the fact remains that there will be an interchange. If you have an abscess sac at the end of a tooth root filled with the products of bacterial activity, you will get a plus and minus interchange. You will get a flowing of the toxins or split proteins through the thin wall of that sac

into the adjacent lymph space, and from there a diffusion which can easily go to the valves of the heart, glomeruli of the kidneys, or which can easily irritate the nerves, or start new bone growth as a walled-off factor against the secretion, that could give you arthritic symptoms in your muscles, that can cause deposition of the calcium urates in the region of the synovial fluids, cause degeneration of any mucosal surface in the body, particularly in the antrum or nose and throat, where polypi may be manifest. That is the working theory which I have in my mind—the mechanism of the process of absorption and of the bacterial absorption around the teeth.

Personally I have had six cases of asthma and acute bronchitis which have been relieved after extraction and curettage. They have been examined in every possible way. We have blood tests and urinary examinations, examinations of saliva, and in five out of those six cases the patients show reaction to pus-forming bacteria. Two were staphylococcus, one was staphylococcus aureus, and the others streptococcus viridans. One patient could scarcely walk across the floor without labored breathing. The men who were working on these patients and trying to check up the possible source of the foci said there must be something wrong with the teeth. The tonsils had been removed in two cases, the appendix had been removed from another, and we could not lay the blame there. Everything had been eliminated which could be blamed as a source of infection.

Now as to the teeth. The teeth had been X-rayed indifferently. I saw some of the original plates. Four interpretations had been made. One case in particular showed very little about the tooth roots, excepting the area on the upper right side extending from the first bicuspid to the second molar. The X-ray did not show anything particularly wrong with that section. Yet the man could scarcely breathe, had to sit up nights, and had not been able to work for two years. He showed a reaction to the streptococcus viridans. On a chance I removed a bridge, and found some de-

vitalized teeth under the bridge. I dissected back the tissues very carefully and came to the mucosa of the antrum, being careful not to break into the antrum, because it had been carefully washed out through the naso-antral wall. I know that that man came to report later on his own account, to tell us how well he was getting along, although he had been for a long time previously in the Massachusetts General Hospital. He was free from all asthma symptoms. I am sure Dr. Turnbull will recall this patient.

That is my testimony, and that is where I wish to connect with the work Dr. Turnbull is doing in his search for the protein reaction. There may be no absorption, and in consequence the micro-organisms will stew in their own juice; they cannot survive. But if the products of their activity do get free and are diffused and go into the system, you may be prepared for a number of things, even iritis. I am now studying this problem at the Massachusetts Eye and Ear Infirmary.

We must be on guard to protect our patients against focal infections within the mouth, because the protein absorptions may include a manifestation of asthma or bronchitis, as Dr. Turnbull and our clinical observations are demonstrating.

DISCUSSION.

Dr. Weston A. Price, Cleveland, Ohio. I wish to express my appreciation of the splendid paper and presentation of Dr. Turnbull. I would like to ask him if he would suggest whether there is a differentiation between different strains of the same organism. Do you find it necessary to differentiate? Also, do you find you can retain the toxin without retaining the body of the protein?

Dr. Turnbull. In regard to the different strains of the staphylococcus and streptococcus, you can make your test and use any stock vaccine.

Dr. Price. Would you say that a vaccine made from any strain of viridans would produce the same reaction?

Dr. Turnbull. We are working on

that, but I am not yet prepared to say; they are very closely related. We have had great difficulty with viridans, and in this work we have had great difficulty in getting media to produce large enough quantities for this work.

Dr. Price. Do you make your test with the vital organism?

Dr. Turnbull. Yes, with protein. We take the bacteria and grow them in quantities, and wash them of media; centrifuge; re-wash, to acquire solution of bacteria. Then add four volumes of ninety-five per cent. alcohol and throw down a precipitate. That is again re-washed with alcohol. The alcohol is thrown off, the precipitate washed with acetone and ether, then washed with ether and acetone again, and again with ether, and then dried. Do not think the toxin has any effect; it is mainly the protein and the absorption of the protein that we are using. We can test these proteins. We can use the same bacterial proteins in dilute forms for desensitization, and get the same results as with vaccines. That is what I have been working on in connection with the growth of the bacteria. One thing we must watch out for is in washing off and getting out a certain amount of the media. I made a number of experiments in that line, using sterile water, precipitating it and throwing down the protein of media bacteria, and had many reactions. No doubt in a number of cases in the inoculations for typhoid and paratyphoid, very many of the disturbances are caused by the media. I think using the protein from which that is all taken out has a better effect. We can weigh out a certain amount and make our dilution, whereas with the bacterial vaccine variations occur.

The meeting then adjourned until 8 o'clock.

FRIDAY—Evening Session.

The meeting was called to order at 8.30 o'clock, by the president Dr. Bryant.

Dr. BRYANT. We are holding a joint session this evening with the Connecticut

State Hygienists' Association. This is the fourth year we have met together, and I wish to extend to the Hygienists' Association, through Mrs. Hart, the president, the courtesy of introducing the speaker of the evening.

Mrs. HART. *Mr. President, ladies and gentlemen.*—I wish to express our appreciation of your courtesy in permitting us to join with you in your annual convention.

Tonight our associations are honored by having as our guest the director of the Research Institute of the National Dental Association, Dr. Weston A. Price of Cleveland. Dr. Price and his co-workers are doing much toward solving many of the problems which confront dentistry, and I am sure it will be an inspiration to all of us to hear him this evening on the subject of focal infections.

I take great pleasure in introducing Dr. Price.

Dr. WESTON A. PRICE of Cleveland, Ohio, made an address on the subject of "Septic Root-canals—Filled and Unfilled—and Their Relation to Localized and Systemic Diseases."

[This lecture is not published here for the reason that no revised manuscript has been received from the author.—ED.]

Mr. L. J. WEINSTEIN, New York. You have all probably heard about the shortage of platinum, and the need of the Government for platinum in the conduct of the war. Dentists are concerned about what is going to happen to them, and there is both a patriotic and personal interest in the matter.

I have fortunately (or unfortunately) been engaged in aiding the Government in the conservation of platinum, and my present task is to give the subject some publicity, with the principal object of asking you to hold whatever platinum you have. Do not dispose of it to anybody until the Government tells you what to do with it.

The material I will read to you may sound peculiar, but it is prepared for publication, and you must bear with me

in the form in which it is written. The article on conservation will be printed in the May *Dental Digest*, and the publishers have agreed to furnish a reprint to every non-subscriber.

Mr. Weinstein then read the article on "Conservation of Platinum in Dentistry," published in the *Dental Digest* for May 1918.

The meeting then adjourned to 9.30 o'clock Saturday morning.

SATURDAY—*Morning Session.*

The meeting was called to order by the president, Dr. Bryant, at 10 o'clock.

The society then took up the report of the Committee on Amendment of the By-laws, and after several revisions and amendments were made it was agreed to leave the final revision for adoption at the next annual meeting.

The Secretary read the list of applications for membership.

Dr. BECKWITH-EWALL. I move that the secretary be instructed to cast one ballot for the list of applicants.

The Secretary cast one ballot, and the candidates were declared elected.

The Secretary read an invitation from the New York State Dental Society, inviting the members of this society to attend their fiftieth anniversary meeting on June 13, 14, and 15, at Saratoga Springs.

A motion was made that the invitation be received and placed on file, and that our president reply to the same with thanks. (Motion carried.)

The Secretary read a letter from the Research Institute asking for a list of historical places or libraries where information could be obtained in regard to the history of dentistry.

The Secretary read a communication regarding the clinicians to be sent to the National Association meeting to be held in Chicago, in August.

Dr. T. A. GAXUNG, Bridgeport. I move that that matter be left to the incoming president. (Motion carried.)

The Treasurer read a list of delinquent members for 1916, '17, and '18, saying that all of them had received registered letters.

Dr. BECKWITH-EWALL. I move that these names as read, of men three years in arrears and taking no interest in the society, be dropped from the roll. (Motion carried.)

REPORT OF THE EXECUTIVE COMMITTEE.

Dr. M. J. LOEB, chairman. The Executive Committee wishes to report that it has audited the Report of the Treasurer, and finds it correct. It also wishes to report that through the efforts of the state board, and also through some other effort on behalf of the State Society, a number of men have been brought to court and fined for practicing illegally.

We have received a considerable amount of assistance from Dr. Geo. B. Palmer, and the Executive Committee wishes to extend in open meeting an expression of thanks to him for his efforts.

Dr. RULE. I move the acceptance of the report, and the adoption of the recommendation made by the committee. (Motion carried.)

The SECRETARY. Would it be possible at this time for the society to purchase another Liberty bond? We have over \$1200 in the savings-bank, and it would seem we could purchase another bond.

I make that as a motion, subject to the judgment of the Board of Censors.

Dr. SEARS. I am personally in accord with the idea of purchasing all the Liberty bonds we can, but we do not know just exactly where we are at the present time. We do not know how fast our money will come in from the exhibitors, or how fast the dues come in. Although we have \$1200 in the bank today, we may not have much left, as many bills may be coming in tomorrow. I would rather put it in a form that if we have sufficient money left after paying our bills, we buy a \$500 Liberty bond. I make that as an amendment. (Motion as amended carried.)

Dr. HUNT presented the following resolution:

Be it RESOLVED, That we, the members present of the Connecticut State Dental Association, after hearing the work and aims of the Dentists' Mutual Protective Alliance discussed, give the Alliance our indorsement, and recommend that every dentist in the State of Connecticut support this organized effort to eliminate process patents from the dental profession.

Dr. A. C. FONES. I am opposed to this society indorsing the action of this Mutual Protective Association until we know more about it. I do not think we want to act on anything like this hastily at the eleventh hour, when we are about to adjourn, without thoroughly investigating it.

I would make that as a motion, that we postpone action on this resolution until next year. (Motion carried.)

REPORT OF THE NOMINATING COMMITTEE.

Dr. GANUNG, chairman of the Nominating Committee, reported as follows:

President—B. A. Sears, Hartford.

Vice-president—G. S. B. Leonard, Mystic.

Secretary—Morton J. Loeb, New Haven.

Treasurer—Frank J. Buchanan, Waterbury.

Executive Committee—J. F. Barton, Hartford, Wm. J. McLaughlin, Bridgeport, Ralph Keeler, New London.

Editor—O. T. Rule, Stamford.

Librarian—John L. Beach, Bristol.

Dr. SCHLOSSER moved that the report of the Nominating Committee be accepted as read, and that the secretary be instructed to cast one ballot for the officers as nominated.

The Secretary cast one ballot, and the officers were declared elected.

The PRESIDENT. I want to take a moment to extend my sincere appreciation to the Connecticut State Dental Association for the support they have given me during the past year. I cannot tell you how much I appreciate it, especially the support of the chairmen of my committees. We have, I think, worked more as a unit than have any committees since I have been in association work. And I

especially want to thank the chairman of the Executive Committee, who took the whole burden of the work while I had to be away for a rest. I assure you I appreciate very much the honor you extended to me, and thank you very much for the support you have given me.

I will ask Dr. Riggs and Dr. George McLean to conduct the president-elect to the chair.

Dr. BRYANT. Dr. Sears, I hope the association will give you the same loyal support they have given me.

Dr. SEARS. I thank you from the bottom of my heart. I will not make a speech. The first thing I will do will be to appoint the chairmen of my various committees, for I am in the Dental Reserve Corps, and I do not know when I may be called away.

I want the meeting next year to be a success, and I want every man in the association—from east to west, and from north to south—to take hold and help.

The following were appointed

CHAIRMEN OF COMMITTEES.

Committee on Essays—Chas. McManus, Hartford.

Committee on Clinics—A. E. Cary, Hartford.

Supervisor of Clinics—E. A. Spelman, Hartford.

Committee on Exhibits—G. O. McLean, Hartford.

Committee on Dental Legislation—A. C. Fones, Bridgeport.

Program Committee—A. A. Hunt, Hartford.

Press Committee—S. L. Beckwith-Ewall, Hartford.

Committee on Entertainment—The President and Hartford Dental Society.

Reception Committee—Chas. A. Humphreys, Hartford.

Committee on New Members—E. P. Anderson, Hartford.

Committee on Necrology—E. S. Gaylord, New Haven.

Dr. McLEAN moved a vote of thanks to the retiring officers. (Motion carried.)

Dr. McLEAN moved a vote of thanks to the DENTAL COSMOS, to Dr. Anthony and his staff, for the publication of the proceedings. (Motion carried.)

Dr. LOEB moved a vote of thanks to the hotel management for its co-operation in making the meeting a success. (Motion carried.)

Dr. BECKWITH-EWALL moved a vote of thanks and appreciation to all the essayists and clinicians who helped to make the meeting a success. (Motion carried.)

There being no further business, the meeting then adjourned.

THE DENTAL COSMOS

A MONTHLY RECORD OF DENTAL SCIENCE.

Devoted to the Interests of the Profession.

EDITORIAL DEPARTMENT

Dentistry in Relation to Reconstruction.

THE United States of America entered the world-war on April 6, 1917. Hostilities ceased November 11, 1918, with democracy triumphant over autoocracy. The principles of human liberty and self-government for which the fathers of our republic fought the war of independence nearly a century and a half ago, and then wrought into the fabric of our national life, have now become the priceless heritage of all civilized mankind. From the agonies of more than four years of war in which the instincts of hellish ingenuity were expended to their limit in devising means to thwart the efforts of humanity to control its own destiny, peace has issued, a new era of new ideals is created, and amidst the joyous acclaim of a liberated world the birth of social and political free-

dom is signalized. Verily, "A woman when she is in travail hath sorrow because her hour is come, but as soon as she is delivered of the child she remembereth no more her anguish for joy that a man is born into the world."

The era of reconstruction now confronting us involves much more than reconstruction in a national sense; it involves a new angle of view toward all of our life problems, a reorientation of the individual as well as of the national attitude of mind toward its new responsibilities. No individual, no field of endeavor can escape the urge of the new world-spirit in shaping the activities of mankind. For nineteen months every interest in this broad land of ours—every individual, has contributed each in his degree toward the winning of the war; the mind, the energy of the nation has been intensively focused on that single objective. All of our resources have been dedicated to the common purpose, and the end has come triumphantly in a moral as well as in a national sense. The world-war thus becomes the background of all future human development and endeavor, because of the revolutionary changes, physical and intellectual, which it has wrought, and for the same reasons it becomes the foreground of a new era in human progress.

In the light of the foregoing it is important to consider the effect upon dentistry wrought by the war period, and what suggestions the experiences thus gained offer for the future direction of dental activities, especially with respect to the larger public relationships of our profession.

We entered the conflict with an organized Dental Surgeons Corps for both the army and navy, and as the essential character of the service as a factor in maintaining the physical efficiency of our fighting units became manifest, it was found that the allotment of dental surgeons to *personnel* was inadequate, so that an increase to approximating ten thousand was authorized in the army dental surgeons corps, the present standard making an allotment of one dental surgeon to each 500 of the army *personnel*.

Government recognition of the essential importance of dental service to the health of the army was further evidenced by the Act of Congress of October 6, 1917, granting increased rank to the dental corps. In the field, in base hospitals, in the cantonments, and throughout the entire military establishment, the service

of the dental corps has justified itself as an indispensable element of the general military medical activity.

Collateral to the organized military dental service of the Government, the Preparedness League of American Dentists was created as a voluntary service by the civilian dental profession—its object being to eliminate the dental disabilities of recruits before their enlistment. We have from time to time published reports setting forth the extent of membership and the results accomplished by this patriotic dental organization. The figures are impressive, but what is of much greater importance as affecting the future status of the dental profession is the convincing argument which the work of the army and navy Dental Corps and that of its adjuvant the Preparedness League of American Dentists offers as to the importance of the public service relationships of dentistry. Before the war, dentistry was subject to no little criticism for its lack of practically expressed interest in public health service; but the war service of dentistry has educated the public to a realization of the importance of dental service, and it has revealed to the dental profession itself the desirability of rendering that service. It is just this great educational result that needs now to be capitalized and organized for the benefit of the public and the dental profession as well.

With demobilization the military objective of the Preparedness League will vanish, but this great organization should be held together and its energies utilized in civilian channels. Divested of its military purposes, its essential reason for existence is still the same, viz, the altruistic service which dentistry can render in connection with the public health. This is concerned with dental service in schools, hospitals, eleemosynary institutions, industrial establishments, and all avenues by which the general public in the larger sense can be reached. The democratization of social, industrial, and commercial activities, now the keynote of the reconstruction period, must also include the democratization of dental service.

Moreover, there is yet much to be accomplished in reorganizing the dental profession and its public service upon an autonomous basis of control; by which we mean the freeing of dental activities everywhere from the hampering interference of medical direction and placing it under the control and supervision of its own membership. No organization is better fitted to do this work on broad

lines than the Preparedness League. Dental societies are handicapped by a local "provincialism" that is not a hampering factor either in the objectives or activities of a nation-wide group such as the Preparedness League. By all means, then, let the League be kept intact, so that its energies may be directed toward the objectives of dental service in the era of peace as they have been so successfully enlisted in the winning of the war.

BIBLIOGRAPHICAL

PRINCIPLES AND PRACTICE OF FILLING TEETH. By C. N. JOHNSON, M.A., L.D.S., D.D.S., Professor of Operative Dentistry in the Chicago College of Dental Surgery; Editor of the *Dental Review*. Fourth Edition, revised and enlarged, with 127 illustrations. Philadelphia: P. Blakiston's Son & Co. Price \$3.00.

The author avows that his principal aim in preparing this book has been "to direct attention to some of the causes of failure in filling teeth, and to offer suggestions relative to possible improvement in methods of procedure." To accomplish this he has systematized and emphasized some of the recent advances in practice. The principal alterations from foregoing editions may be itemized as follows: (1) The chapter on the Cast Gold Inlay has been entirely rewritten (Taggart's process is followed); (2) the subject of Root-canal Filling has been changed and elaborated; (3) Oral Prophylaxis has received a recognition more worthy of its importance.

It would have been better to have omitted any reference to the etiology of dental caries than to present that vital,

intricate, and even yet obscure subject in the totally erroneous and misleading form offered in this work. From the description the beginner would never gain the concept that substances of a carbohydrate nature, acted on by zymogenic bacteria, yield the acid to dissolve the inorganic constituents of enamel and dentin. There is absolutely no mention of the second phase of the disintegrating process, viz, the proteolytic action of bacteria on the organic matrix of dentin. And the bacterial plaque, which localizes the organisms, is ascribed to the long-ago exonerated "gelatin"-forming micro-organisms. As far as concerns the etiology of dental caries in a work of this nature, the sin of omission would have been insignificant in comparison with the sin committed. This incident, while trivial in itself under the circumstances, exemplifies the most serious criticism which can be made of this work.

While in numerous statements Johnson has acknowledged the right by virtue of the doctrine of oral foci of systemic disease to select and to eliminate any given operative or prosthetic method, he has neglected to apply this criterion in all instances. For instance, "As a tem-

porary sealing agent in the treatment, it (gutta-percha) is, without question, the best material we possess" (page 146) is a statement which will be questioned by those who have a proper regard for the exclusion of micro-organisms from the canals during treatment. The importance of this is recognized by Johnson on page 252, but in a somewhat different connection.

In the chapter on the Destruction of the Pulp there is no mention of anesthetization by nerve-blocking. Johnson depends on arsenic trioxid and pressure anesthetization with cocain or novocain, with a predilection for the arsenic trioxid. For the sterilization of putrescent canals Johnson relies on Buckley's tricresol and formalin. Some will think that too much optimism and tolerance are manifested toward porcelain inlays. The sterilization of dentin after cavity preparation and before insertion of the filling material deserves far more consideration and insistence than it receives on pp. 126-9. In reality we find but a single sentence given to this subject.

Cavity preparation is a subject which today does not permit of much latitude in presentation. Yet in a modern textbook it would seem advisable to establish its principles upon the rational basis of the minute structure and architecture of enamel and dentin. (See F. B. Noyes, "Dental Histology and Embryology," 1915, ch. 6 to 11, incl.) The importance of this is here more casually implied than emphasized. The illustrations of this chapter could with advantage be more numerous and on a larger scale.

Methods are described simply and clearly. They are presented with the informality and vividness of a practical demonstration. This humanizing influence is repeatedly illustrated by the in-

junction to the future practitioner to consider the preferences and even the whims of the patient wherever such acquiescence will not lower the quality of the work. Nowhere does this attitude find more persuasive expression than in the section dealing with hypersensitive dentin (pages 129-36).

Blakiston's books are well produced, and this is no exception to that rule. The whole appearance of the book is most pleasing and satisfactory.

Books Received.

Books received are acknowledged in this column, and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender. Selections will be made for review in the interests of our readers and as space permits.

"Mammalian Dentition." By T. WINGATE TODD, M.B., Ch.B.Manch., F.R.C.S.Eng., Captain, Canadian Army Medical Corps, Henry Willson Payne Professor of Anatomy, Western Reserve University, Cleveland, Ohio; formerly Lecturer in Anatomy, Victoria University of Manchester, England. With 100 illustrations. St. Louis: C. V. Mosby Co., 1918. Price \$3.00.

"Practical Dental Metallurgy." A Text and Reference Book for Students and Practitioners of Dentistry, Embodying the Principles of Metallurgy and Their Application to Dentistry, Including Experiments. By JOSEPH DUPUY HODGEN, D.D.S., Professor of Operative Dentistry (formerly Professor of Dental Chemistry and Metallurgy), College of Dentistry, University of California. Revised by GUY S. MILLBERRY, D.D.S., Professor of Chemistry and Metallurgy and Dean of the College of Dentistry, University of California. Fifth Edition, completely revised. St. Louis: C. V. Mosby Co., 1918. Price \$2.50.

"The Surgery of Oral Diseases and Malformations, Their Diagnosis and Treatment." By GEORGE VANINGEN BROWN, D.D.S., M.D., C.M., F.A.C.S., Major, Medical Officers' Reserve Corps, U. S. Army, Oral Surgeon to St. Mary's Hospital and to the Children's Free Hospital and Columbia Hospital, Milwaukee, etc. Third Edition, with 570 engravings and 20 plates, and a selected list of examination questions. Philadelphia and New York: Lea & Febiger, 1918. Price \$7.00.

PRACTICAL HINTS

This Department specially welcomes the brief presentation by our readers of any novel suggestions or methods which in their own practice have proved to be time-saving or to possess other features of advantage.

A Dental Trocar.

By L. D. CORIELL, D.D.S., Baltimore, Md.

DURING the last four or five years, as we all know, there have been noted an unusual number of systemic diseases having had their origin from dental infections, and as a result there has been a slaughter of the so-called infected teeth where the diagnosis has been made exclusively by radiographs. Having had fourteen years' experience in radiographic work, I know that in a great many cases a radiograph is practically worthless as a diagnostic aid, and as a result of this known fault, after two years of experimenting, I have evolved the instrument that I have called the "Coriell Dental Trocar," which I shall endeavor to describe, explaining the technique necessary for its use.

We know that it is impossible to get an uncontaminated culture from periapical tissue through the root-canal, and we also know how difficult it is to get one from an extracted tooth, it being almost impossible to extract without contamination. I have therefore adopted the only way possible I know of to get a culture uncontaminated, *i.e.* through the alveolar process.

The instrument that I use is a small trephine driven by the dental engine in a right-angle handpiece. The trephine has the hole in it closed by a twist drill

that projects about 1 mm. beyond the tooth end of the trephine; after the trephine has been driven into the suspected area the drill is withdrawn, leaving the trephine in place, a platinum needle is inserted through the trephine into the suspected area, and culture taken in the usual way.

FIG. 1.

FIG. 2.

FIG. 3.

In detail, Fig. 1 represents the drill, Fig. 2 the trephine, Fig. 3 the assembled trocar, and Fig. 4 the trocar in the hand-piece. Figs. 5 and 6 show the method of obtaining the culture.

The technique in detail is as follows: After having selected the spot over the apex of the root from which we wish to obtain our culture, we first inject a small quantity of novocain or some other

suitable local anesthetic some little distance from the spot where we are to make our puncture. After anesthesia has been obtained, we cauterize, either with iodine

driven. We now take a platinum needle (having previously passed it through a Bunsen or alcohol flame three or four times) and pass it through the trephine

FIG. 4.

FIG. 5.

FIG. 6.

or trichloroacetic acid, preferably the latter, the spot where the trocar is to be driven in. The trocar and handpiece having been thoroughly sterilized in a suitable dry-heat sterilizer, we drive the

and into the suspected area, then withdraw it and inoculate suitable culture

FIG. 7.

FIG. 8.

trocar into the spot previously cauterized sufficiently deep to feel the point against the tooth structure. The engine is then stopped and the drill unscrewed from the trephine, leaving the trephine in the position to which it has been

media with the culture thus obtained. I usually inoculate three different types of media, *i.e.* beef bouillon, glucose agar

(for the anaerobes), and blood agar for the hemolytic organisms, and stab each one, two or three times.

If the above technique is properly carried out, it is the only way I know of

was made direct from the first tube inoculated, without any plating (it shows staphylococcus aureus). Fig. 9 is a radiograph of a central incisor from which the culture shown in Fig. 10 was obtained. This is a mixed infection,

FIG. 9.

that it is possible to be certain that the growth obtained is free from contamination with other oral micro-organisms. The proof I have of this is that on numerous occasions I have obtained organ-

FIG. 11.

and was likewise obtained without plating or transplanting.

I have a number of these cases equally interesting, but simply submit these two as being typical.

FIG. 10.

isms in pure culture from the originally inoculated tubes, without dilution or plating. Fig. 7 shows radiograph of molar from which the culture in photomicrograph Fig. 8 was taken. This slide

FIG. 12.

In conclusion I will say that a good many cases where I have attempted to obtain growths from teeth that were infected (according to radiographic evidence) the results have been negative, and in a greater number of the teeth

where the radiographic evidence has been negative I have had luxuriant growths in from twenty-four to forty-eight hours. Fig. 11 is a radiograph of such a case, and Fig. 12 a very poor picture of a diplo-bacillus obtained from it. (This case was one of severe arthritis, and had a violent reaction after taking the culture, but finally showed a decided improvement after the tooth was extracted.)

The data that I have obtained in this way has convinced me more and more

fully that the radiograph in a great many cases is worse than valueless, and unless we can back up our evidence with some definite method, such as the one described, any opinion that we may give regarding such cases is nothing more nor less than a guess. If we care to make a microscopic examination of the tissue involved, we can get our specimen from the flutes of the drill, and if we find tissue change, plus bacteria, we have disease.

516 PARK AVE.

The Use of the Drill as an Aid to Tooth Extraction.

By ISIDORE CLIFFORD, L.D.S., R.C.S.Eng., London, Eng.

I WISH to make known to every member of the profession my experience in using drills before extracting teeth. It converts the present method of extraction (which is a combination of skill and brute force) into a simple scientific surgical operation. I have proved its success over and over again, and feel sure that every dentist will be thankful to know that he need never again struggle with an obstinate tooth.

Before extracting any tooth that I suspect may give the slightest trouble I drill away the labial or buccal plate of the alveolus, and then with a pair of forceps the tooth is easily removed through the opening thus made—without any chance of breaking it. My *modus operandi* is as follows: With a strong lancet I clear the gum from the tooth and alveolus, then take a large-size pointed cross-cut fissure bur from which the temper has been drawn (heating it to a dull red heat draws the temper and sterilizes it), and drill away the bone, keeping the bur close to the roots of the

tooth. In the case of molars I make sure that the alveolus between the roots is carefully severed; about five-eighths of an inch is the usual depth to drill. It does not take half a minute to do this, though the temper of the drill has been drawn. (If the drill is hard it is liable to break.)

When I need to use an elevator, I drill a hole in the alveolus in exactly the position I want to place my elevator.

The most fragile or strongest tooth can now be extracted quite easily, as it makes no difference if the roots be curved or exostosed. This drilling is not necessary in any simple case, but I am sure every dentist will be delighted with the result of the drilling in every other case. There is far less bleeding than one would expect to find, and the removal of the alveolus is really an advantage, because it later has to be absorbed or exfoliated.

I feel I am doing a humanitarian act in giving this method the widest publicity.

REVIEW OF CURRENT DENTAL LITERATURE

[*Transactions of the American Laryngological Association.* (Thirty-ninth meeting, 1917.)]

Three Bronchoscopic Cases of "Dentists" Origin. BY B. R. SHURLY.

As these three cases occurred during the last decade in a city of an average population during this time of 500,000 people, and as we have an estimated population of over 100,000,000, it might be fair to conclude that possibly six hundred cases of similar accident had occurred in the United States and Canada perhaps, during a similar period. In the discussion of Shurly's paper, mention was made of eleven similar cases.

Shurly believes that the probable frequency of this accident indicates that the possibilities of disaster in ordinary dental procedure were sufficiently great to inaugurate some preventive measures of additional safety. Two of his three cases (as that of Thomson) were not discovered by the dentist or patient at the time of operation. To avoid this, he suggests that some detailed method of observation and counting in the extraction of teeth be devised, similar to that provided by the abdominal surgeon in the case of sponges and instruments. Thomson supplements this with the observation that it would not entirely cover the field, as not only teeth on extraction are inspired, but also crowns and bridges, burs, broaches, pieces of vulcanite and cements and plaster of Paris.

The line of action which a dentist should follow if he thinks, or even suspects, that a tooth or other object has entered the air passages, is indicated by the following seven "don't's" from Chevalier Jackson's work ("Peroral Endoscopy and Laryngeal Surgery," St. Louis, 1915, p. 235).

(1) Do not reach for the foreign body with the finger.

(2) Do not make any attempt at removal with the patient in any other than a re-

cumbent position, with head and shoulders lower than the body.

(3) Do not hold up the patient by the heels, lest the foreign body be dislodged and asphyxiate the patient by becoming jammed in the glottis.

(4) Do not fail to have a radiograph taken.

(5) Do not fail endoscopically to search for a foreign body in all cases of doubt.

(6) Do not pass an esophageal bougie, probang, or other instrument blindly.

(7) Do not tell the patient he has no foreign body until after radiography, physical examination, indirect examination, and endoscopy have all proved negative.

To this list Thomson adds the injunction, The patient should *not* be encouraged to cough or hawk up.

In summary, the best the dentist can do in such an emergency or suspected emergency is to hand the patient over at the earliest moment to a skilled laryngologist.

[*Practitioner*, London, August 1918.]

Tooth Impacted in a Secondary Bronchus of the Left Lung; Removal by Lower Bronchoscopy. BY ST. CLAIR THOMPSON.

The patient was a girl of ten years. The tooth, a deciduous left mandibular first molar, was inspired following the extraction of the tooth. Both patient and dentist were ignorant of this inspiration for the period of about one month. Respiratory and pulmonary symptoms had existed from the first. A radiograph revealed an opacity in the region of the root of the left lung, of rather indefinite outline, and roughly rectangular in shape.

Direct bronchoscopy, using a 7 mm. Bruening tube, under chloroform, through the mouth, five weeks after the accident, showed a white glistening tooth tightly impacted in an externo-lateral secondary branch of the left bronchus (it is decidedly rarer to en-

counter foreign bodies in the left lung than in the right) at a depth of $10\frac{1}{2}$ in. from the teeth. All attempts at removing the tooth at this sitting failed.

A second peroral examination, eight days following the first, was a failure. The patient suddenly collapsed, and had to be restored by artificial respiration before an attempt at removal could be made.

The formation of a lung abscess forbade further delay. The third examination was in brief as follows: Under chloroform, tracheotomy was performed. This permitted the introduction of a 10 mm. Bruening tube. The tooth was found at a distance of $5\frac{1}{2}$ in., and was relatively easily removed with a pair of Killian's "bean forceps." The after-history was uneventful. The scar on the neck is insignificant.

Maxillo-dental-facial Malformations. By
PIERRE ROBIN.

By maxillo-dental-facial malformations, Robin means all the irregularities of the teeth and of the jaws which distort the esthetic harmony of the face, as well as the form and volume of the cavities contained therein. These malformations are considered especially in their relation to diseases of the digestive and respiratory systems, of olfaction, of audition, as well as to the vicious attitudes of the thorax so frequently assumed in the case of children. The immediate consequences of these malformations are the imperfect preparation of the food bolus and of the inspired air.

It is imperative to correct these malformations as early as possible. Robin's method can be applied as soon as the eruption of the deciduous teeth is completed. His appliance, which is not technically described in this paper, acts not upon the teeth directly, but upon the jaw-bones themselves (the alveolar processes?), which thereby are slowly expanded. The appliance is inserted totally within the mouth, is worn all night, and as much as possible during the day; it is always removed when eating. The results are to Robin very satisfactory.

A priori, this appliance seems promising. The method meets the desideratum of Bogue (*DENTAL COSMOS*, February 1917, p. 246) of early treatment of malocclusion, which is only

one item of Robin's maxillo-dental-facial malformations, even during the period of the deciduous teeth; apparently it is of simpler technique and of less annoyance to patients of such tender age; and finally, it is not impossible that moving a segment of the alveolar process with its teeth *in toto* is more logical than that of moving the teeth alone, as well as provocative of periodontal traumatism.

Robin's appliance appears to fulfil the conditions exacted by modern orthodontia. J. V. Mershon (*DENTAL COSMOS*, October 1918, p. 934) says "The ideal appliance is one which interferes the least with the normal functions of the tissues and organs of the mouth." The possibility of removing it whenever desired would permit the institution and inculcation of those exercises and habits so admirably presented by A. P. Rogers (*DENTAL COSMOS*, October 1918).

Vincent's Angina: Report of a Case. By
J. M. KING.

The case is unusual for (1) its long course, the patient being seriously ill for about four months; (2) death from exhaustion, no special complication occurring (no autopsy was permitted); and (3) its resistance to neosalvarsan, three maximum doses being given a week apart without staying the progress of the disease. It is interesting to compare the symptoms and findings in this case, set forth below, with those enumerated by Barker and Miller (see pp. 1160-61).

The patient was a woman of twenty-six years; complained of sore-throat, fever, cough. Temperature 103° , cervical glands slightly swollen, whole pharynx covered with a slight membranous exudate, and on upper pole of right tonsil a small superficial ulceration. Smears showed abundance of Vincent's organisms (a condition persisting to time of death). Urine at first contained a small amount of albumin, a few hyaline and an occasional granular cast, but later was normal. At all times, leucocytosis of 12,000, of polymorphonuclear nature. The blood gave a weakly positive Wassermann. In course of observation the temperature was irregular, from normal to 104° . Pulse rose from 100 to 130 or so. Respiration mounted to 40. Anorexia

persisted. Vomiting was a rather marked feature. The local lesion before death had spread across the pharynx, involving the left tonsil, ate away the uvula, involved the soft palate, and invaded the larynx.

[*British Dental Journal*, June 15, 1918.]

A Case of Meningitis Associated with the Presence of *Bacillus Fusiformis*. BY CECIL WORSTER-DROUGHT.

In this case no definite primary focus beyond dental caries and pyorrhea alveolaris could be demonstrated even at autopsy. The patient was a man of thirty-two years. Apparently no microscopic examination was made of the "well-marked pyorrhea," which may or may not have been due to a Vincent's infection. This is unfortunate, as it would afford the first link in the chain connecting the "pyorrhea" with the meningitis. The spinal fluid showed numerous Gram-positive cocci, some lanceolate and in pairs, others in small chains. Gram-negative coliform bacilli, and many Gram-negative fusiform bacilli. No spirochetal forms were seen. There is nothing recorded in this report which would prove or disprove the implication that meningitis was secondary to an oral Vincent's infection.

[*El Siglo Médico*, Madrid, July 6, 1918.]

Facial Paralysis in a Syphilitic. BY E. F. SANZ.

The patient, a man of forty-six years, had suffered for four years of hemiplegia with aphasia, from a cerebral syphilitic lesion. A series of injections of gray oil was given, five days after the first of which there appeared a paralysis of the left half of the face. Synchronously with this there was an exacerbation of the oral conditions, which were already in a bad state. The gums became turgid, dark red, with numerous ulcerations. Severe pain with tumefaction of the left upper jaw region was felt. The mouth was dry.

Sanz diagnosed the condition as a parotitis consecutive to mercurial stomatitis (*vide infra*, Barker and Miller's paper). The facial paralysis might on this assumption be attributed to a compression of the branches of the facial nerve by the inflamed parotid.

Mercurial medication was halted. A scrup-

ulous disinfection of the mouth was instituted. Warm external applications were made in the region of the parotid. Very soon the stomatitis ameliorated. The inflammatory reaction of the parotid receded; step by step with this the facial paralysis became less marked, confirming Sanz' diagnosis.

[*Journal of Experimental Medicine*, October 1, 1918.]

Experimental Parotitis. BY MARTHA WOLLSTEIN.

This work is summarized by the author as follows: A new series of inoculations of the filtered, sterile [free of microscopically visible organisms?] salivary secretions derived from cases of parotitis (including the epidemic parotitis of our military camps) has been described.

Confirmatory evidence of the filterable nature of the causative agent of mumps has been obtained. It has been determined that the saliva of man and of inoculated cats, and the inoculated glands of the latter animals, contain the filterable infective agent. The "virus" of parotitis was detected most readily in the saliva during the first three days of the disease, less easily on the sixth day, and not at all on the ninth day. It was detected also in the blood of patients showing marked constitutional symptoms, and in the saliva of a case of recurrent mumps at the periods of enlargement of the parotid glands, but not two weeks after the swelling had subsided. It was not detected in the cerebrospinal fluid.

[*Journal of the American Medical Association*, September 7, 1918.]

Perforating Ulcer of the Hard Palate Resembling Tertiary Syphilis, but Due to a Fuso-spirillary Invasion. BY LEWELLYS F. BARKER AND SYDNEY R. MILLER.

The patient was a man of forty-seven years, who presented himself on account of an ulcer on the roof of his mouth, of the development of which he had been conscious for only a few days, and which had gradually become larger and more painful. Physical examination revealed slight anisocoria, rather marked oral sepsis and gingivitis, an unpleasant, fetid odor of the breath, and a well-defined punched-out ulcer, about the size of a dime, situated on the hard palate, covered with a

thick, creamy, easily removed exudate, and surrounded by a deep red, somewhat indurated areola. The base of the ulcer bled easily. The clinical picture justified the suspicion of syphilis, but the Wassermann was negative. The patient was afebrile, and not sick. Smears showed the fusiform bacillus and the spirochetes of Vincent. The lesion promptly healed under treatment with dichloramin-T and local applications of concentrated arsphenamin solutions.

It is well known that the organic arsenicals are almost a specific for Vincent's infections. Consequently the rapid clearing-up of the lesion is to be ascribed rather to the arsphenamin than to the dichloramin-T, which in such cases at the Evans Dental Institute School of Dentistry, University of Pennsylvania, has proved unavailing.

This single case history has served the authors merely to introduce a concise and very well proportioned review of the subject. They recognize that it has been established without a doubt that one condition above all others exerts an influence favorable for the development of this type of ulcerative stomatitis, namely, oral sepsis, periodontal gingivitis, or pyorrhea. This fact has been pointed out by Bowman (*DENTAL COSMOS*, June 1918, p. 534).

The symptomatology is as follows. Objectively one notes—

(1) Insignificance, as a rule, of constitutional disturbances; the patient is not very ill. (For possible exceptions, see reports of cases by Worster-Drought, King, and Sanz on pp. 1059-60.)

(2) Absence of fever, rarely over 100-101°.

(3) Heavy and offensive breath.

(4) Enlargement of the cervical and submaxillary glands, as a rule moderately; they are tender and never suppurate.

(5) The lesions proper.

(6) Swollen, spongy and bleeding gums, suggestive of scurvy.

Subjectively the patient complains of—

(1) Extremely bad taste in mouth.

(2) Tenderness of the gums, so that the use of a toothbrush is impossible, and mastication is so painful as to preclude eating.

(3) Pain in swallowing.

(4) Looseness of the teeth, with salivation, which is common resembling mercurial pyalism (*vide infra*, laboratory finding No. 2).

(5) Anorexia.

(6) Joint pains, frequently.

(7) Lassitude—lack of "go."

(8) The most serious constitutional symptom, and one always present when the teeth and gums are affected, is severe depression.

The laboratory findings are—

(1) Uniformly negative blood cultures.

(2) The Wassermann in all cases of Vincent's disease is negative in nonsyphilitic patients. The presence of a positive reaction does not exclude Vincent's disease, and experience has shown that patients with a syphilitic history, undergoing mercurial treatment, are especially prone to this form of mouth lesion. (In other words, "mercurial" stomatitis is strictly a Vincent's infection of the gingival tissues, whose resistance has been lowered by the specific treatment.) Cf. Sanz' report [opposite page].) It is acknowledged that the treatment with mercury can be pushed to a far greater extent in cases with healthy mouths than in those with mouths filthy with oral sepsis. This is explicable on the views of Bowman and of Barker and Miller themselves, viz, that oral sepsis strongly favors Vincent's infection. The question of the Wassermann reaction in Vincent's infection has received some attention, and the view held by the authors is that advocated by Taylor and McKinstry (*DENTAL COSMOS*, May 1918, p. 449).

(3) The leucocytes are rarely increased over 10,000; anemia does not develop in the majority of cases.

(4) A transient albuminuria is common in the more severe cases.

(5) Smears from the lesions show the characteristic organisms, a fusiform bacillus and a coarse spirochete, in association with numerous other organisms.

(6) Dark-field illumination aids greatly in eliminating the treponema pallidum.

As the identity of the two organisms mentioned above in (5) is undecided, and since the postulates of Koch have in no sense been fulfilled, the crucial demonstration that these organisms are the specific cause of Vincent's disease is at present lacking. This much is known—

(1) In all of the lesions under discussion the organisms are present, as a rule, in enormous numbers, and often virtually in pure

culture, The severer the infection, the greater the number of organisms.

(2) There is positive evidence both as to the infectiousness and contagiousness of Vincent's disease.

(3) Healing of the lesions goes on parallel with the disappearance of the organisms. When complete, no organisms remain.

These facts may be taken as adequate proof that if the organisms are not the only, they are certainly an essential factor in the causation of these lesions, which constitute a clinical picture distinctive enough to be considered an entity, and so regarded by the consensus of present opinion.

Two sentences are of particular interest to the dentist. The first injunction, under the heading of Treatment, is: "A good dentist is one of the best therapeutic measures; the

care of the mouth is essential." And the admonition which receives the emphatic position of concluding the article is: "Prophylaxis is better than cure: oral sepsis is inexcusable."

[*Bulletin of the Johns Hopkins Hospital*,
October 1918.]

Multiple Primary Malignant Tumors. BY R. H. MAJOR.

The single case upon which this extensive analysis of 196 similar cases throughout the literature is based, concerned a woman of sixty years, who was suffering from carcinoma involving the right side of the nose, and extending to the inner canthus of the right eye. Necropsy showed an unsuspected round-celled sarcoma of the stomach.

PERISCOPE

Relieving Pain of Devitalized Pulp.—

When a patient returns to the office with an aching tooth as the result of a treatment for devitalization, conduction anesthesia may be used with good results. If properly performed the aching subsides in a few minutes, after which the tooth may be thoroughly and painlessly opened up. A new treatment can then be placed in the tooth, or if sufficient anesthesia is present, the pulp can be removed at once. In either instance, a patient relieved of pain will leave the office.—ALBERT E. CONVERSE, *Dental Review*.

Instructions in Re-sterilizing Compound.—

(1) Thoroughly clean all plaster from compound, breaking any extra large pieces of compound so that there are no pieces larger than an egg.

(2) Place in a pot—a double boiler is preferable, as it prevents the compound from burning at the bottom—and cover well with a solution of glycerite of naphthol (benetol) composed of one ounce to one gallon of hot water.

(3) Bring to a boil as rapidly as possible and boil thirty minutes. *Note:* Be sure the water is really boiling, as the small pieces of

plaster left in the compound will cause numerous bubbles to rise.

(4) Pour the water off and pour out the compound, which should be a spongy mass, on a sheet of galvanized iron or clean planed board, previously covered with Russian oil.

(5) Knead thoroughly the same as dough, when the plaster that may have been left in will work to the surface in the form of a bubble. Be sure to keep the hands well covered with Russian oil to prevent the compound from sticking, and start kneading as soon as it can be handled. Do not use soap and water to prevent the compound from sticking, as the lye in the soap will destroy the oils in the compound.

(6) As soon as the compound begins to show signs of stiffening, roll out on an oiled surface, and just before hardening run a knife across the same, marking off squares of desired size.

An excess of Russian oil incorporated in the compound will seriously retard its setting qualities. An excess of oil may be extracted by again bringing the compound to a boil. Only enough oil should be used to keep the compound from sticking to the table and hands.—W. E. CUMMER, *Oral Health*.

Removing Bad Lateral Root.—An upper lateral root which the X-ray showed to be infected as well as crooked, absolutely resisted all usual methods of removal.

At a hardware store a very small "machine screw tap" was purchased, also one or two short machine screws to fit the thread which this screw would cut. With a large fissure bur the canal was carefully enlarged, and a real screw-thread carefully cut in the sound dentin of the tooth. The tap was then removed, and one of the machine screws firmly set up tight in this threaded root. The protruding head of the screw offered a splendid hold for the ordinary forceps, and the root came out entire and without fracture.—ARTHUR G. SMITH, *Dental Review*.

Removing Plaster from Vulcanite Dentures.—The dental laboratory worker sometimes finds, on removing a plate from the flask after vulcanization, that the mold or model plaster has formed a hard and strongly adherent layer of crystals on the surface of the vulcanite. Prevention is, of course, better than cure, and one ought not to be so careless as to leave the flask in water for some hours after vulcanization. In cases where one can afford to wait for the gradual action of a slow solvent, the following method will be found very satisfactory: The well-washed plate should be immersed in a strong or saturated solution of sodium hyposulfite—photographers' "hypo"—and left in this solution overnight. On removal from the solution, it will be found that in many instances the incrustation has been entirely dissolved. Should some crystals remain on the plate, they no longer adhere closely, and they can be readily brushed away, leaving the vulcanite surface quite clean.—*Oral Health*.

How to Fit and Apply Angle's Ribbon Arch.—All bands are to be fitted and soldered at the chair. Make anchor bands out of coin gold, 32-gage, soldering buccal tubes thereto. A more accurate fit can be obtained by following this procedure than by using ready-made bands. Place anchor and bracket bands on the teeth, and take a plaster impression. Put on two coats of shellac and one of sandarac varnish, let the impression stand over night, then run a model in Weinstein's artificial stone.

Place one end of the ribbon arch in the buccal tube, and by careful annealing and bending it can be sprung to place in each bracket. Remove from the brackets and place the other end of arch in the buccal tube. Loosen up the nuts and anneal with blowpipe.

Iron-bending wire should be used to hold the arch in the brackets, for the reason that it will not sweat the parts together. The ribbon arch treated in this way will fit perfectly, and will not put a strain upon any part until manipulated by the operator.—J. BERTRAM STEVENS, *Internat. Journ. of Orthodontia*.

Matrices for Amalgam Fillings.—In my opinion the method of fastening matrices with a ligature is sloppy and uncertain. The ligature is liable to slip off and give way. Besides, the 36-gage copper advocated is unnecessarily thick. A better way is to use a soldered steel matrix, which can be made of thinner material and is secure, as well as quickly and easily made. You can make up a stock of them of all sizes you may need, as follows: Get one of the stands used for holding seamless caps, which consists of an oblong flat piece of wood with numbered upright cylindrical blocks. Get a sheet of the thinnest matrix steel. The S. S. White Co. has it of a thinness almost of writing paper. Cut the steel into strips of convenient length, pinch around the blocks, remove, hold the pinched portion in appropriate pliers, flux the joint with solution of zinc chlorid made by dropping a piece of zinc into hydrochloric acid, apply a small piece of soft solder, and solder over alcohol lamp. Do not trim the soldered portion flush, but leave quite a little projection to give plenty of strength. You will, after a short experience, be able to pick a matrix which will fit or approximately fit the tooth you are working on. If the one you selected does not fit the tooth, find which of the cylindrical blocks it does fit. From that you can determine the exact size you want. You can then trim it if necessary to avoid irritation of the gum: place on the tooth, shape the end of a stick of orange-wood to fit between the teeth, and hold the cervical part of the matrix against the gingival wall, preventing overhang of filling. Do not cut your orange-wood wedge to interfere with contour. With the wedge in place, you are ready, after drying, etc., to fill. You will need about twelve sizes. Of those about six are most frequently used. You may rarely need a size larger than the largest of the blocks, which of course is easily made. It may sometimes be necessary to cut the matrix before removing after hardening of the filling. Generally I am able to remove without cutting after the filling has been left to harden sufficiently.

The matrix can then be washed, sterilized in flame or boiling water, and used several times.—VINCENT FISCHER, *Dental Review*.

"**The Psychology of the Child**" is something that should be incorporated in a progressive school of orthodontia, inasmuch as we are dealing with children at ages when they are most impressionable. Further, we are working under a nervous strain, and we may so arrange our surroundings, our office fixtures, the decorative scheme, etc., as not to be conducive to relaxation, and this reacts not only on ourselves but on those coming into the office. Every person entering a professional or business office is impressed favorably or unfavorably, irritated or rested, by the surroundings. Personally, if I go into a room in which the pictures are hung on the wall at an angle or placed in an inappropriate location, I do not rest very comfortably. Those things are affecting us at all times, and if we ourselves are irritated those whom we serve will be unconsciously affected in a similar way. I believe certain malocclusions are produced by a child's surroundings, inasmuch as they show similarity in voice, features, and various expressions of those whom they admire. I believe certain class III cases are produced through the imitation of the child, through the fondness of the child for a grandparent or parent in whom this type of malocclusion was present.—WM. CAVANAUGH, *Pacific Dental Gazette*.

A Plaster Bite for Bridge Work.—In constructing bridge work, it is often difficult to transfer crowns or attachments from the abutment teeth to a working model with certainty as to maintaining their proper position and relation throughout the procedure. For small or moderate-sized bridges, a plaster bite, taken as follows, will be found efficient and reliable for this purpose:

With the crowns or attachments securely and accurately in position upon the abutment teeth, mix plaster moderately stiff, and with a suitable spatula apply generously over the abutments and surrounding tissues which are necessary to be reproduced in the model, and have the patient bite the opposing teeth to place.

When the plaster has set, remove the bite, and replace the attachments in the impression. If the attachments pull off in the bite, be sure to press them firmly back into position, and secure with hard wax before running the model. In some cases it may be necessary to split the plaster to remove the bite, but this is generally of little consequence, as the plaster can easily be pieced together with hard wax.

The advantages of this method are certainty of maintaining proper position and relation

of attachments, and at the same time obtaining an accurate impression of the opposing teeth.

If that portion of the bite which contains the impression of the opposing teeth is run up in some hard model material such as Weinstein's artificial stone or Spence compound it will be an advantage, for when plaster is used, this portion of the model is often rendered useless by abrasion or breakage.—C. W. COLTRIN, *Dental Review*.

The Inlay Abutment.—This attachment is indicated for both the anterior and posterior part of the mouth, and is especially designed for short bridges, but at times can be used for longer ones. In the posterior teeth, the inlays are placed in the occlusal approximal surface, and in the anterior teeth on the lingual side approximating the space to be bridged. The tooth is prepared for the inlay and a tube of suitable size is dropped to the floor of the pulp chamber, and a little distance into the enlarged canal. The cavity is then filled with inlay wax, running it well around the tube, and carving to restore the normal contour of the tooth. The whole is then removed, the tube filled with asbestos paper or fiber, after which it is flaked and east. It is then cleansed, placed in the mouth, and articulated. The impression is taken with the inlay in place, and after removing the impression from the mouth the inlay is waxed in it and the model prepared. The work from this point on is done on the model. We are now ready to prepare the second inlay.

The cavity is ground in the first inlay, following the general shape of the tooth cavity, leaving a thick enough margin of gold all around to give strength to the inlay. It is then smoothed and polished. The entrance to the tube is slightly enlarged, a split pin is fitted in it and bent at right angles to the tube, the extending surplus metal resting in the groove. The second inlay can now be made by waxing carefully, removing, and casting around the pin. Another method which the writer prefers is to fit a pure gold matrix into the cavity of the first inlay. The pin is passed through the bottom of this matrix and into the tube. It is then waxed carefully with hard sticky-wax, removed, invested, and filled with coin gold, after which it is cleansed, replaced in the original inlay, and finished. The bridge is soldered to the inlay.

This technique of inlays as abutments is not at all dependent on the casting process. The casting process is of very little service when applied to removable work where great accuracy is essential.—F. A. PESO, *Journ. N. D. A.*

OBITUARY

Major Harold W. Estey, D.D.S.

DIED, in France, Monday, October 28, 1918, of pneumonia, Major HAROLD W. ESTEY, D.D.S.

Major Estey was a well-known Boston dentist, who was graduated from Harvard Dental School in 1897, and had practiced his profession in Boston for a number of years. Major Estey's military service began in 1897 as a private in the Reserve Corps Cadets, in which organization he became captain of Company A. Soon after the declaration of war Major Estey was detailed for service in France, being promoted to the rank of major. Soon after his arrival in France he was detailed to a French staff war college, and after completing the course of instruction, was regulating and liaison officer connected with the general staff. In April 1918 he was decorated by the French government for extreme bravery under fire.

Major Estey is survived by his widow, three young sons, three sisters, and a brother.

Dr. William Henry Wright.

DIED, at his home, Brandon, Vt., May 11, 1918, in his seventy-fifth year, of heart trouble, Dr. WILLIAM HENRY WRIGHT.

Dr. Wright was born in Shoreham, Vt., August 25, 1843. He obtained his early education in the district school of Whiting, Vt., and Brandon Seminary. He studied dentistry under a preceptor in Middlebury, Vt., and in February 1865 opened an office for the practice of dentistry at Brandon, Vt., where he continued in active practice for forty-eight years.

Dr. Wright was long and favorably known in the dental circles of Vermont, being a member of the Rutland County Dental Society and a member of the Vermont State Dental Society, serving the latter society as president in 1894. Although actively engaged

in the practice of his profession, Dr. Wright was largely interested in farming, real estate, and politics. He was one of the founders of the Cloud County Bank of Concordia, Kansas, and had served in the capacities of vice-president and president of this bank for twenty-five years. He was also president of the First National Bank of Brandon, Vt., for more than fifteen years. He was a member of the House of Representatives from 1912-14, and was a member of the Vermont State Senate in 1915-16.

Dr. Wright was married to Miss Alma Esther Smith of Brandon, Vt., in 1873, and is survived by his widow and two sons.

"In Memoriam" Resolutions.

Dr. Robert M. Scott.

At the regular meeting of the Dental Society of Chester and Delaware Counties (Pa.), held September 25, 1918, the following *in memoriam* resolutions were adopted.

Whereas, in the providence of an all-wise Creator, our fellow member Dr. Robert M. Scott died June 29, 1918; and

Whereas, his ability and skill as a practitioner and his keen interest in professional affairs placed him in the front rank among the members of this society; now therefore be it

RESOLVED, That we, the members of this society, feel deeply his loss, and hereby express our appreciation of his worth, and our sorrow over the untimely close of a successful career; and be it further

RESOLVED, That a page on our minute-book be set aside, and the secretary be instructed to inscribe thereon these resolutions, and that a copy be sent to his widow, also to the professional journals for publication.

JUSTIN E. HARLAN,
A. HERBERT GRUBB.
DAVID Y. SAHLER.

ARMY AND NAVY DENTAL NEWS

Camp Fremont Dental Corps Notes.

By RAOUL H. BLANQUIE, 1st Lt. D. C., Camp Fremont, Cal.

THE 8th Division at Camp Fremont, Cal., was one of the last cantonments to receive its full quota of dental surgeons. For several months the entire amount of dental work was handled, as best could be, by a few army dentists. The actual commencement of the dental corps was marked by the assignment to this division of Major C. M. Taylor, D.C., as acting division dental surgeon last April. A U. S. army division comprises 27,500 men, and is entitled by table of organization to 31 dental surgeons, and as many dental assistants.

In May dental officers began reporting for duty, and then started the division dental surgeon's task of organizing the corps. Upon arrival in camp each dental surgeon was placed on attached service to a definite organization and made attendant to approximately 1000 men. A complete field dental equipment was furnished him, which was set up in a room in the infirmary of his organization, or if this was not available, a special tent was placed at his disposal. In order to expedite the work in a systematic way, each dental surgeon undertook a survey of his organization, giving every man a complete examination and recording on a chart the necessary work to be performed. Later, those requiring immediate attention were treated first. The following compiled data will give an idea of the amount of work confronting the dental corps at this camp.

Records for 14,339 men were obtained. The division consists of 27,500 men. Therefore, this left 13,161 yet to be tabulated.

| | |
|----------------------------------------------------------|--------|
| Number of carious teeth | 21,402 |
| " " extractions | 6,053 |
| Abscessed teeth and those with putrescent pulps | 2,295 |
| Pyorrhea, true | 679 |
| Extensive salivary deposits | 873 |

Number of impacted 3d molars not tabulated: one dental surgeon of the 320th Field Sig. Bn. found 13 upon examination of 800 men.

No tabulation of number of dentures needed.

In June the permanent "division dental infirmaries," consisting of two large buildings, were completed and occupied. It may be said that these buildings are the best constructed in this camp. They are roomy, well lighted and ventilated, and furnished with hot and cold running water. The hours of duty are as follows: 7.45 A.M. to 12 M. 1 P.M. to 4 P.M. 4 to 5 P.M., exercises and drill.

The corps during July has had its numbers depleted, owing to transfer of some of its members. Nevertheless, work has been progressing substantially, as can be judged by the record of the month of July, viz:

| | |
|------------------------------------|-------|
| Dental surgeons working | 28 |
| Total number of persons treated .. | 2,301 |
| " " " sittings given .. | 5,282 |
| Sundays and holidays, total ..days | 9½ |
| Actual hours worked | 165 |

| <i>Diseases.</i> | |
|-------------------------------------------|-------|

| Repairs to denture | 1 |

Twice weekly, meetings are held under the direction of Major Taylor, after regular hours. Regulations of the service and the court-martial manual were at first taken up at length. Papers are read and discussed, each dental surgeon preparing a paper on a subject relative to oral surgery or army dentistry, and one being read at each meeting.

The base hospital of this division carries two dental surgeons. These men are constantly in consultation with the medical staff in cases of patients suffering with systemic disturbances from focal infections, and are rendering a great assistance in clearing up these cases. Here is also established a well-equipped dental laboratory where a great number of partial dentures with lingual bars, and full dentures, are made for those in need of them in the division.

All credit for the work accomplished is due to Major C. M. Taylor, who has

endeavored assiduously to make the dental corps at Camp Fremont a smooth-running and efficient organization.

It is the hope and desire of each member in this corps to see active service overseas very soon.

Italy Honors General Gorgas.

IN recognition of his distinguished services in behalf of military sanitation, Major-general William C. Gorgas, until recently Surgeon-general of the United States Army, has been made a Grand Officer of the Order of the Crown of Italy. The ceremony of presentation took place November 5th, in the office of the Surgeon-general, the order being presented by Major General Emilio Guglielmotti, military attaché of the Royal Italian embassy.—*Army and Navy Register*.

Sources of New Dental Officers.

DECISION was reached this week by the military authorities, upon recommendation of Col. William H. G. Logan, medical corps, head of the dental section of the Surgeon-general's office, in regard to the methods to be followed in obtaining the additional dental officers needed as a result of the recent increase in the military forces. By orders recently issued the allowance of dental officers was increased to one for every 500 men in the United States, three for each camp hospital, and three per thousand for each general hospital, and the allowance for the forces overseas also was increased, the new allowance amounting approximately to one for every 500 of the total strength of the army. Under the new schedule, a total of some 10,000 dental officers will be needed by July 1, 1919, or about 3500 more than now are on active duty and temporarily commissioned in the dental corps and still on an inactive status. The regulations that will govern new appointments are based on the premises that those dentists that are in, or will be taken as a result of the draft into, the military service should first be given opportunity to qualify for commissions in the dental corps. Therefore opportunity for commissions will be confined to those dentists that now are serving in the enlisted grades, and to those that may come in through the draft. If the vacancies are not all filled from these classes, then dentists within the draft ages and rated in class 1-A and not called to service, and those between forty-six and fifty-five years of age, will be given the opportunity to take examination for appointment. There are now about seventy vacancies in the dental corps of

the regular army. Candidates, who will be limited generally to those now temporarily in the service, will be examined, commencing November 4th, by boards that have been ordered to meet at Fort Slocum, N. Y.: Camp Meade, Md.; Fort Oglethorpe, Ga.; Camp Lee, Va.; Columbus Barracks, Ohio; Fort Sam Houston, Texas; Camp Funston, Kans.; and Letterman General Hospital, San Francisco.—*Army and Navy Register*.

Naval Dental Corps.

PROGRESS is being made in the naval dental school, recently established at the naval training station, Great Lakes, where about thirty young dental officers are under instruction. The first course will be completed in a week or two, and another class will be formed. The courses are six weeks in length, and consist of both naval and professional subjects, the purpose being to prepare newly appointed dental officers for their duties afloat and ashore in the navy. The dental corps of the navy now consists of about 500.—*Army and Navy Register*.

Army Medical Department.

CHANGES in the duties of the officers of the army medical department in the important billets in this country, expected as a result of the appointment of General Ireland as Surgeon-general of the Army, are destined to be made with great deliberation, if made at all to any extent. General Ireland proposes to proceed without violence in his administration of the affairs of the department, and so far only the necessary orders are being issued. The most important of the week is the assignment of Col. Winford Smith, formerly superintendent of the Johns Hopkins Hospital, as head of the hospital division of the Surgeon-general's office, as the successor of General Noble, who has gone to France. General Ireland has been succeeded as chief surgeon of the American Expeditionary Force by Col. Walter D. McCaw, it has been announced. It is not made known to what duty General Noble will be assigned.—*Army and Navy Register*.

Promotions.

ARMY DENTAL CORPS.

The following appointments (promotions) are announced (October 19th):

To be CAPTAINS—for existing emergency: 1st Lieuts. Julius D. Goldman, George M. Frith, Richard C. Hughes, Vincent A. Hannigan, Edward B. Riblet, Wm. E. Mentzer, Aaron R. Crane, Frank M. McFarland, Floyd E. Clinite, Charles T. Miles, John E. O'Flinn, Atwell L. Benton, Harry V. Talbert, John A.

Zwisler, Wm. P. Higgins, Ross O. Dickson, Charles B. Amis, Robert E. Giddens, Frank Vaughan, Henry H. Faeteau, Benjamin F. Pound, and Andrew I. Denney.

Announced October 26th:

To be MAJORS—for existing emergency: Captains Frederick L. Litty, David A. Proctor, Wm. F. Blair, John F. Connolly, Clyde E. Duncan, Idus W. Shields, Earle Robbins, John J. Collins, and Kyle B. Alsobrook.

Announced November 2d:

To be CAPTAINS—for existing emergency:

1st Lieuts. Jacob L. Brause and Clifford Strange.

Announced November 9th:

To be CAPTAINS—for existing emergency: 1st Lieuts. Wm. S. Carrick, Ralph L. Faulkner, Charles W. Marriott, and John C. Zeidler.

Assignments.

Week ending November 9th.

The following to Fort Oglethorpe, Ga., for instruction: Majors Oscar G. Skelton, Emmett P. Varvel, Walter L. Reesman, and Harry M. Deiber.

Preparedness League of American Dentists.

ORGANIZED UNDER THE AUSPICES OF THE N. D. A.

Preparedness League Notes and News.

By R. OTTOLENGUI, *Publicity Committee.*

FROM THE PRESIDENT.

AMERICA is to be the greatest nation of the world. Why? Because we are giving freely to help the rest of the world. Without the untold sacrifices we have made and the billions upon billions we have laid on the altar of humanity, we could not become great. Have we done this in a spirit of selfishness? No! We have done it without thought of reward. We are exemplifying our conception of the Golden Rule.

Do you think the millions of women working patiently month after month for the greatest organization in the world . . . the American Red Cross . . . are looking for personal benefit? Do you think that body of self-sacrificing girls and women who never think of themselves . . . our noble nurses . . . are looking for self-aggrandizement as reward for their labor of love?

Let us not debase our own thoughts by permitting even a suggestion of such things. You know it is not possible.

Where, then, does each one of us stand in relation to the world's work that is before us? Each one knows just how much he has done and what motives prompted him in doing it. This is a matter unto himself. But no matter how much we have done, we must do more. The only limit is our physical capacity.

The October number of the *Literary Digest* prints an article entitled "Europe Admiring Yankee Teeth." The teeth of our boys have

been an object of admiration by the other armies, and the article makes special mention of the splendid services of American dentists. This is encouraging to us and indicates that our efforts are appreciated, and should prompt us to do more than ever to send our boys away in as good condition as possible.

Do you know that when our boys have toothache while in the trenches, their teeth are extracted and they are sent back immediately? It does not matter if it is a front tooth that is aching—it must go, even though it could be treated and filled. When those boys return to civil life, they will be badly handicapped. We must avoid such a situation as far as possible by doing our duty by them before they leave their home town for camp. This is the duty of the League.

In a recent letter from a member of the dental corps now in France, he says: "The League is not forgotten over here. I have met many of our soldiers who had their teeth fixed by its members, and they are very grateful. I have met others who did not take advantage of the opportunity, and they are very sorry." The work you do for them is fully appreciated when they are "over there." Let us spare no effort to help our boys.

STUDY CLASS IN POST-WAR DENTAL WORK.

A course of practical instruction in the most recent and approved methods of war oral surgery has been arranged by the Royal

College of Dental Surgeons, Toronto, Canada, and the Preparedness League of American Dentists, during the week of December 16-21, 1918. That it may be international in character, instructors of unquestioned ability from the United States as well as Canada will collaborate in the object of giving American dentists the benefits of such knowledge in oral surgery as has been gleaned from actual experience at the front.

Canada now commands a large amount of clinical material, which is constantly being augmented by the many wounded soldiers being returned from overseas. The teaching and laboratory facilities of the Royal College of Dental Surgeons have been given over to this object, and the operative clinics will be given in Toronto Hospitals. The number will be limited to one hundred, which will be divided into classes of twenty-five each, thereby

insuring the personal attention of the instructors for each member.

Col. W. H. Thompson, in command of the dental corps of Ontario, has extended the privileges of the numerous military clinics and the full assistance and co-operation of the military for the purpose of making this course most practical in character. Major E. W. Cummer will instruct in prosthesis and Col. G. G. Hume, who has returned from three years' service overseas, will have much of practical value to impart.

This is an exceptional opportunity, and members of the League should take advantage of it. A fee of fifty dollars will be charged, which goes to the instructors.

Announcement will later be made relative to carrying on this course in the principal cities of the United States.

J. W. BEACH, *President.*

American Red Cross.

Demonstration in dental clinic at St. Etienne.

SPECIAL NOTICE.

Rescinding of "Platinum — Iridium — Palladium" Regulations.

WAR INDUSTRIES BOARD, WASHINGTON, D. C.

[We are authorized to publish the following official order rescinding the regulations governing the sale, possession and use of "platinum, iridium and palladium or compounds thereof" as published in our previous issue.—Ed.]

(I.)

The following Order was issued November 14, 1918:

Because no longer required for the public safety, the Director of the Bureau of Mines, in charge of Explosives Regulation, has made the following changes in the General Information and Rulings under the Act of October 6, 1917 (40 Stat. 385) and as amended by the Sundry Civil Act of July 1, 1918.

1. All regulations relating to ingredients not used or intended to be used in the manufacture of explosives are revoked and no further license of such ingredients will be required.

2. All regulations relating to fireworks are revoked and no further license of fireworks will be required.

3. All regulations relating to Platinum, Iridium and Palladium, and compounds thereof, are revoked and no further license for Platinum, Iridium and Palladium will be required.

Approved:

VAN H. MANNING.

Director.

FRANKLIN K. LANE,

Secretary of the Interior.

CLARENCE HALL,

Chief Explosives Engineer.

(II.)

The effect of the foregoing Order is to render void any licenses heretofore issued to you under the so-called Platinum Rules and Regulations, dated August 17, 1918; to render unnecessary further compliance with said Rules and Regulations, and to terminate the necessity for securing further licenses thereunder.

(III.)

The foregoing Order shall not operate to relieve any person upon whom an order requisitioning Platinum, Iridium and Palladium, or compounds thereof, may have been served, from any obligation imposed upon him by such order.

PLATINUM SECTION:

C. H. CONNER, *Chief.*

SOCIETY NOTES AND ANNOUNCEMENTS

NOTICES should reach the Office of the DENTAL COSMOS not later than the 11th or 12th of the month preceding that of publication.

American Institute of Dental Teachers.

THE next annual meeting of the American Institute of Dental Teachers will be held at Hotel Piedmont, Atlanta, Ga., January 28, 29, and 30, 1919.

Papers on the teaching of war dentistry and an exhibit of war appliances will be the main features, and along with these will be the usual papers on teaching methods. All persons interested are cordially invited.

ABRAM HOFFMAN, *Sec'y*,
381 Linwood ave., Buffalo, N. Y.

Dental Protective Association.

THE annual meeting of the Dental Protective Association of the United States will be held at the Palmer House, State and Monroe sts., Chicago, on December 16th, at 4 P.M. Reports of officers will be presented, a board of directors elected, and such other business transacted as should come before the association. All members are urgently requested to be present.

J. G. REID, *President*,
J. P. BUCKLEY, *V.-pres. and Sec'y*,
D. M. GALLIE, *Treasurer*.

Ohio State Dental Society.

THE fifty-third annual meeting of the Ohio State Dental Society will be held in the Memorial Hall, Columbus, December 3, 4, and 5, 1918.

An excellent program of papers and clinics is assured, with some new features of special interest.

A cordial invitation is extended to members in good standing of other state societies to meet with us.

F. R. CHAPMAN, *Sec'y*,
305 Schultz Bldg., Columbus, Ohio.

California Board of Examiners.

THE next meeting of the Board of Dental Examiners for the purpose of examining applicants for a license to practice dentistry in the State of California will be held in the city of San Francisco at the Dental College, University of California, beginning on December 9, 1918. All applications for examination must be filed with the board on December 9th at 9 A.M. Each application must be accompanied by (1) the fee of \$25; (2) diploma and license from other states; (3) diploma from an accredited high school giving a four-year course of instruction or a certificate signed by a state superintendent of public instruction (or similar officer) to the effect that such applicant has had scholastic preparation in all respects equivalent to that demanded for graduation from an accredited high school giving a four-year course of instruction, in the state from which such certificate is issued; in lieu of such high-school diploma or certificate, an applicant who has been licensed in some other state of the United States for a period of at least five years may file his state license; (4) a testimonial of good moral character; (5) a recent unmounted photograph.

By order of the Board of Dental Examiners of California.

C. A. HERRICK, *Sec'y*,
133 Geary st., San Francisco, Cal.

Montana Board of Examiners.

OWING to the present war conditions and the lack of a sufficient number of applicants, the Montana Board of Dental Examiners will *not* hold the usual January examinations. The next examinations will be held at Helena, Mont., on July 14, 15, 16, and 17, 1919.

T. M. HAMPTON, *Sec'y*,
Helena, Mont.

North Carolina Board of Examiners.

THE next meeting of the North Carolina State Board of Dental Examiners will be held at Raleigh, N. C., beginning promptly at 9 o'clock on Thursday morning, January 9, 1919.

For further information and application blanks address

F. L. HUNT, *Sec'y*,
Asheville, N. C.

Pennsylvania Board of Examiners.

THE next examination of the Pennsylvania Board of Dental Examiners will be held in Philadelphia and Pittsburgh, on Tuesday, Wednesday, Thursday, and Friday, December 3, 4, 5, and 6, 1918, at Musical Fund Hall in Philadelphia and the University of Pittsburgh, Pittsburgh. The practical examination will be held on Friday, December 6th, the last day. Application papers can be secured from the department of Public Instruction, Harrisburg.

For further information address

ALEXANDER H. REYNOLDS,
4630 Chester ave., Philadelphia, Pa.

New Jersey Board of Registration.

THE State Board of Registration and Examination in Dentistry of New Jersey will hold their annual meeting and examination in the Assembly chamber, at the State-house, Trenton, N. J., on December 2, 3, 4, 5, and 6, 1918. License fee, \$25; re-examination fee, \$10. Practical tests required: Insertion of an approximal gold filling, with approximating tooth in position, compound approximal amalgam filling, a silicate filling, practical test of the applicant's ability in oral prophylaxis, and preparation of a cavity for an inlay with wax pattern. Also the soldering of a bridge consisting of three or more teeth exclusive of abutments, and one Richmond crown, which may be one of the abutments of the bridge; these must be made of gold or silver. The bridge must be struck from dies made from an impression of the mouth, and the articulating model, with the bridge, when soldered, must be submitted for inspection. An anatomical articulation of a

full upper and lower set of teeth will also be required; teeth to be furnished by applicant. Wax bite properly trimmed and in place on models for inspection before setting up teeth.

Attention is directed to the following quotation from the dental law of New Jersey:

"Applicant shall present to said board a certificate from the Commissioner of Education of this state, showing that before entering a dental college he or she had obtained an academic education consisting of a four-year course of study in an approved public or private high school, or the equivalent thereof." In accordance with this law the secretary will issue application blanks only upon presentation of the required certificate from the Commissioner of Education, State-house, Trenton, N. J.

Note.—Dental Radiography will be added to the list of theoretical examinations in June 1919.

Applications must be filed complete ten days before the date of the examinations. Address all communications for further particulars to

JOHN C. FORSYTH, *Sec'y*,
430 E. State st., Trenton, N. J.

Oklahoma Board of Examiners.

THE Oklahoma Board of Dental Examiners will hold their next regular semi-annual meeting at the State Capitol building, Oklahoma City, Okla., beginning December 9, 1918. Reciprocity only with Kansas, Missouri, Arkansas, Nebraska, Indiana, and District of Columbia.

For further information address

H. OVERBEY, *Sec'y*,
Ryan, Okla.

Delaware Board of Examiners.

THE next meeting of the Delaware State Board of Dental Examiners will be held on January 15, 1919. Candidates for examination must give written notice of their desire to take the examination at least two weeks before the date of meeting, accompanied by the examination fee of \$25. The place of meeting will be given upon notice of intention of taking the examination.

W. S. P. COMBS, *Sec'y-Treas.*,
Middletown, Del.

Rhode Island Board of Registration.

THE semi-annual meeting of the Rhode Island Board of Registration in Dentistry, for the examination of candidates, will be held at the State-house, Providence, R. I., December 3, 4, and 5, 1918.

Applications with fee must be in the hands of the secretary one week previous.

For further information address

ERNEST A. CHARBONNEL, *Sec'y*,
139 Mathewson st., Providence, R. I.

Registration of Dentists—December.

ATTENTION is called to the following amendment to Chapter 181 of the General Laws of 1909, entitled "Of the Regulation of the Practice of Dentistry":

SECTION 3. Every person engaged in, or licensed to engage in if not actively engaged in, the practice of dentistry in this state shall

annually in the month of December of each year, beginning December 1918, and every person who shall hereafter engage in the practice of dentistry in this state shall before so engaging and thereafter annually in the month of December of each year, beginning December 1918, cause his name, address, and place of business, if in business for himself, and if not in business for himself then his name, and the name, address, and place of business of his employer, to be registered with said board, which shall keep a book for that purpose; and each person so registering shall pay said board a fee of one dollar at the time of each registration, and shall receive a certificate of registration for the next succeeding calendar year from said board.

Those interested will please notify the secretary of their addresses.

ERNEST A. CHARBONNEL, *Sec'y*,
139 Mathewson st., Providence, R. I.
